**ABSTRACT.** In this article, we prove that every 3-connected planar graph has a closed walk visiting each vertex, none more than twice, such that any vertex visited twice is in a vertex cut of size 3. This generalizes both Tutte's Theorem that 4-connected planar graphs are Hamiltonian and the result of Gao and Richter that 3-connected planar graphs have a closed walk visiting each vertex at least once but at most twice.

### 1. INTRODUCTION

Tutte [Tu] proved that every 4-connected planar graph is Hamiltonian. Recently, Gao and Richter [GR] settled a conjecture of Jackson and Wormald [JW] by showing that every 3-connected planar graph has a *closed 2-walk* — a closed walk that visits every vertex at least once but at most twice. In this paper we prove a common refinement of these results, which was conjectured by Thomas [T]. A  $k$ -cut in  $G$  is a set  $A$  of vertices such that  $G - A$  is not connected and  $|A| = k$ .

**Theorem 1.** *Let  $G$  be a 3-connected planar graph and let  $x, y$  be two vertices both incident with the same face of  $G$ . Then there is a closed 2-walk  $W$  in  $G$  visiting  $x$  and  $y$  only once each, such that every vertex visited twice by  $W$  is in a 3-cut in  $G$ .*

That Theorem 1 generalizes Tutte's Theorem is obvious: if  $G$  is 4-connected and  $W$  is the closed 2-walk guaranteed by Theorem 1, then  $W$  must be a Hamilton cycle, since  $G$  has no 3-cuts and, therefore,  $W$  can have no repeated vertices.

The same ideas improve Thomassen's Theorem [Th] that 4-connected planar graphs are Hamilton-connected. A *2-walk* is a walk visiting each vertex at least once but at most twice.

**Theorem 2.** *Let  $G$  be a 3-connected planar graph and let  $x$  and  $y$  be any vertices of  $G$ . Then there is a 2-walk  $W$  in  $G$  from  $x$  to  $y$  such that any vertex visited twice by  $W$  is in a 3-cut of  $G$ .*

We remark that the proofs given in this paper are substantially simpler than those of [GR]. However, their proofs form the core for the results by Brunet et al [BEGMR], where it is proved that every 3-connected graph that embeds in either the torus or the Klein bottle has a 2-walk. It would be of substantial interest to know if Theorems 1 and 2 generalize to these graphs.

## 2. CIRCUIT GRAPHS

We shall in fact prove our results for circuit graphs, a class of planar graphs that includes the 3-connected planar graphs.

A *circuit graph* is an ordered pair  $(G, C)$  consisting of a 2-connected planar graph  $G$  and a cycle  $C$  of  $G$  such that, in some embedding of  $G$  in the plane,  $C$  bounds a face and, for every 2-cut  $A$  in  $G$ , every component of  $G - A$  contains a vertex of  $C$ .

Obviously, if  $C$  is a face boundary of a 3-connected planar graph  $G$ , then  $(G, C)$  is a circuit graph. Circuit graphs have some very nice inductive properties. The ones relevant for this work are stated in the following result. Proofs can be found in [GR]. A *plane chain of blocks* is a graph, embedded in the plane, with blocks  $B_1, B_2, \dots, B_k$ , such that, for each  $i = 2, 3, \dots, k$ ,  $B_{i-1}$  and  $B_i$  have a vertex in common, no two of which are the same, and, for each  $j = 1, 2, \dots, k$ ,  $\bigcup_{i \neq j} B_i$  is in the infinite face of  $B_j$ .

**Lemma 3.** *Let  $(G, C)$  be a circuit graph.*

- (1) *Let  $G$  be embedded in the plane with  $C$  bounding the infinite face and let  $C'$  be any cycle of  $G$ . Let  $H$  be the subgraph of  $G$  contained in the closed disc bounded by  $C'$ . Then  $(H, C')$  is a circuit graph.*
- (2) *If  $v \in V(C)$ , then  $G - v$  is a plane chain of blocks  $B_1, \dots, B_k$ . Moreover, one of the neighbours of  $v$  in  $C$  is in  $B_1$  and the other is in  $B_k$ .*

## 3. TUTTE PATHS AND TUTTE CYCLES

In order to prove Theorem 1, we shall first prove the existence of a "Tutte path" and a "Tutte cycle" in a circuit graph. For a subgraph  $J$  of a graph  $G$ , a  *$J$ -bridge* in  $G$  is a component  $K$  of  $G - V(J)$ , together with the edges of  $G$  joining a vertex of  $K$  to a vertex of  $J$  and the ends of such edges. If  $L$  is a  $J$ -bridge, then the vertices in  $V(L) \cap V(J)$  are the *vertices of attachment* of  $L$ .

We remark that the usual definition of  $J$ -bridge allows the possibility of an edge, not in  $J$ , together with its ends, which are in  $J$ . Such bridges are of no concern to us, and, to simplify the later discussion, we have chosen not to include them in the definition used in this article.

A *Tutte path* (*Tutte cycle*) in a circuit graph  $(G, C)$  is a path (cycle)  $P$  such that every  $P$ -bridge has at most 3 vertices of attachment and any  $P$ -bridge containing an edge of  $C$  has at most 2 vertices of attachment.

We abbreviate system of distinct representatives to SDR. If  $J$  is a subgraph of a graph  $G$ , then a SDR of the  $J$ -bridges is a SDR of the sets  $\{V(L) \cap V(J) \mid L \text{ is a } J\text{-bridge}\}$ .

**Theorem 4.** *Let  $(G, C)$  be a circuit graph and let  $x, u \in V(C)$ , let  $y \in V(G)$  with  $x \neq y$  and let  $a \in \{x, u\}$ . Then there is a Tutte path  $P$  in  $G$  from  $x$  to  $y$  through  $u$  and a SDR  $S$  of the  $P$ -bridges such that  $a \notin S$ .*

*Proof.* The proof proceeds by induction on  $|E(G)|$ . The unique smallest circuit graph is  $K_3$ , for which the result is trivial. For the inductive step, we may suppose  $G$  is embedded in the plane so that  $C$  is the boundary of the infinite face.

If  $u = x$ , then pick any other vertex of  $V(C - x)$  and let it be  $u$ . (Of course we do not change  $a = x$ .) Thus, we can assume that  $u \notin \{x, y\}$ . The case  $u = y$  and  $a \neq u$  can be similarly dismissed, while if  $a = u = y$ , then interchange the roles of  $u$  and  $y$  and proceed as above.

For any two distinct vertices  $r, s$  of  $C$ , let  $rCs$  denote the clockwise path in  $C$  from  $r$  to  $s$ . Thus, the two paths in  $C$  between  $x$  and  $u$  are  $xCu$  and  $uCx$ . We can assume that the drawing is such that  $y$  is not in  $xCu$  and that  $uCx$  has length at least 2. Let  $u_1$  be the neighbour of  $u$  in the path  $uCx$ . It is possible that  $u_1 = y$ , in which case we let  $K = \{u_1\}$ ,  $\hat{P} = \{u_1\}$  and  $\hat{S} = \emptyset$ .

If  $u_1 \neq y$ , then let  $K$  be the minimal connected union of blocks of  $G - xCu$  containing both  $u_1$  and  $y$ . (Throughout this work, if  $H$  is a subgraph of a graph  $G$ , then  $G - H$  denotes the subgraph  $G - V(H)$  of  $G$ .) Clearly,  $K$  is a plane chain of blocks  $B_1, B_2, \dots, B_\ell$ , with  $u_1 \in V(B_1)$  and  $y \in V(B_\ell)$ . For  $i = 1, 2, \dots, \ell - 1$ , let  $v_i$  be the vertex common to  $B_i$  and  $B_{i+1}$ . Set  $v_0 = u_1$  and  $v_\ell = y$ .

If  $B_1 \cap C$  is not just  $u_1$ , then let  $k$  be the largest index such that  $B_k$  contains an edge of  $C$ . Otherwise, set  $k = 1$ . Let  $w$  be the vertex in  $B_k$  nearest  $x$  in  $uCx$ .

For  $1 \leq i \leq \ell$ , either  $B_i$  is just  $v_{i-1}v_i$  and its ends or  $(B_i, C_i)$  is a circuit graph, where  $C_i$  bounds the infinite face of  $B_i$ . In the first case, let  $P_i = (v_{i-1}, v_{i-1}v_i, v_i)$  and  $S_i = \emptyset$ .

For  $i \in \{1, 2, \dots, \ell\} \setminus \{k\}$ , the inductive assumption yields a Tutte path  $P_i$  in  $B_i$  from  $v_{i-1}$  to  $v_i$  and a SDR  $S_i$  of the  $P_i$ -bridges in  $B_i$  such that either  $v_i \notin S_i$  (if  $i < k$ ) or  $v_{i-1} \notin S_i$  (if  $i > k$ ).

Inductively there is a Tutte path  $P_k$  in  $B_k$  from  $v_{k-1}$  to  $v_k$  through  $w$  and a SDR of the  $P_k$ -bridges in  $B_k$  such that  $w \notin S_k$ .

Let  $\hat{P} = \bigcup_{i=1}^{\ell} P_i$  and  $\hat{S} = \bigcup_{i=1}^{\ell} S_i$ . Set  $\hat{K} = K \cup xCu_1$ .

We now extend  $\hat{P}$  back to  $x$ . For each  $\hat{K}$ -bridge  $L$  in  $G$ ,  $L \cap \hat{K}$  consists of at most one vertex, which we call  $a(L)$ . Let  $\hat{L}$  be the bridge (if there is one) containing the path  $wCx$ . Because  $(G, C)$  is a circuit graph, this is the only  $\hat{K}$ -bridge in  $G$  that can have only two vertices of attachment. If  $\hat{L}$  has only two vertices of attachment, then we shall do nothing with it;  $w$  will be its representative.

Let  $F'$  denote the union of  $xCu$ , all  $\hat{K}$ -bridges in  $G$  and all  $\hat{P}$ -bridges in  $K$  that contain a vertex  $a(L)$  that is not in  $\hat{P}$ . Let  $F = F' - \hat{P}$ . Let  $a_1, a_2, \dots, a_s$  be the cut vertices of  $F$  that are in  $xCu$ , in the order they appear from  $x$  to  $u$ . Note that  $a_1, \dots, a_s$  do not include  $x$  and  $u$ , i.e. they are internal to the path  $xCu$ . Let  $a_0 = x$  and  $a_{s+1} = u$ .

Either there is a path in  $F$  from  $a_{i-1}$  to  $a_i$  that is disjoint from  $a_{i-1}Ca_i$  (except for their common ends) or there is not. If there is not, then  $a_{i-1}$  and  $a_i$  are consecutive vertices of  $xCu$  and we set  $Q_i$  to be the path  $(a_{i-1}, a_{i-1}a_i, a_i)$  and  $R_i = \emptyset$ .

Otherwise, let  $A'_i$  be the block of  $F$  containing  $a_{i-1}Ca_i$  and let  $A_i$  be the union of  $A'_i$  and any  $A'_i$ -bridge in  $F$  that does not contain either  $a_{i-1}$  or  $a_i$ . There is a  $\hat{K}$ -bridge  $L_i$  that has an edge in  $A'_i$ . If there is no vertex  $a(L_i)$ , then clearly  $A_i = A'_i$ . If there is a vertex  $a(L_i)$  and it is not in  $\hat{P}$ , then clearly  $A_i = A'_i \cup (M_i - \hat{P})$ , for some  $\hat{P}$ -bridge  $M_i$  in  $K$ . Finally, if  $a(L_i)$  is in  $\hat{P}$ , then, because  $(G, C)$  is a circuit graph, for each vertex  $p$  of  $L_i$ , there are three disjoint paths from  $p$  to the vertices  $a_{i-1}, a_i, a(L_i)$ . Therefore,  $L_i - a(L_i)$  is 2-connected. It follows that  $A_i = A'_i$ .

Let  $C'_i$  be the cycle bounding the infinite face of  $A'_i$ , so that  $(A'_i, C'_i)$  is a circuit graph.

If  $\hat{L}$  has at least 3 vertices of attachment, then  $\hat{L} - w \subseteq A_1$ . Let  $z$  be the vertex of  $A'_1 \cap C$  such that  $zCx = A'_1 \cap C$ . (It is possible that  $z = x$ , in which case  $zCx$  is also just  $x$ .) Inductively, there is a Tutte path  $Q_1$  in  $A'_1$  from  $x$  to  $a_1$  through  $z$  and a SDR  $R_1$  of the  $Q_1$ -bridges of  $A'_1$  such that either  $x \notin R_1$  (if  $a = x$ ) or  $a_1 \notin R_1$  (if  $a = u$ ).

Now we treat the remaining  $A'_i, i = 1, 2, \dots, s+1$ ; we need to deal with the case  $i = 1$  only if  $\hat{L}$  has only two vertices of attachment. We remind the reader that we are assuming that  $(A'_i, C'_i)$  is a circuit graph, as otherwise we have already obtained the path  $Q_i$  and the SDR  $R_i$ .

If  $A_i \cap K$  is not empty, then  $A_i = A'_i \cup (M_i - \hat{P})$ . Let  $z$  be the vertex in  $A'_i \cap M_i$ . If  $A_i \cap K$  is empty, then let  $z$  be any vertex in  $C'_i$ . Inductively, there is a Tutte path  $Q_i$  in  $A'_i$  from  $a_{i-1}$  to  $a_i$  through  $z$  and a SDR  $R_i$  of the  $Q_i$ -bridges such that either  $a_{i-1} \notin R_i$  (if  $a = x$ ) or  $a_i \notin R_i$  (if  $a = u$ ).

The required Tutte path in  $G$  is  $P = (\bigcup_{i=1}^{s+1} Q_i) \cup (u, uu_1, u_1) \cup \hat{P}$  with  $S = (\bigcup_{i=1}^{s+1} R_i) \cup \hat{S} \cup \{w\}$  as the required SDR of the  $P$ -bridges in  $G$ .  $\square$

The following consequence of Theorem 4 is the heart of the proof of Theorem 1.

**Corollary 5.** *Let  $(G, C)$  be a circuit graph and let  $x, y \in V(C)$ . Then there is a Tutte cycle  $T$  in  $G$  and a SDR  $S$  of the  $T$ -bridges in  $G$  with  $x, y \in V(T)$  and  $x, y \notin S$ .*

*Proof.* Let  $x$  have neighbours  $u$  and  $v$  in  $C$ . The graph  $G - x$  is a plane chain of blocks  $B_1, B_2, \dots, B_k$ , with  $u \in V(B_1)$  and  $v \in V(B_k)$ . Let  $j$  be least such that  $y \in V(B_j)$ . For  $i = 1, 2, \dots, k-1$ , let  $v_i$  be the vertex common to  $B_i$  and  $B_{i+1}$ , let  $v_0 = u$  and  $v_k = v$ .

For  $i = 1, 2, \dots, k$ , if  $B_i$  is just the edge  $v_{i-1}v_i$  and its ends, then we set  $P_i = (v_{i-1}, v_{i-1}v_i, v_i)$  and  $S_i = \emptyset$ .

Otherwise, for  $1 \leq i < j$ , by Theorem 4 there is a Tutte path  $P_i$  from  $v_{i-1}$  to  $v_i$  in  $B_i$  having a SDR  $S_i$  of the  $P_i$ -bridges in  $B_i$ , such that  $v_i \notin S_i$ . Let  $P_j$  be a Tutte path in  $B_j$  from  $v_{j-1}$  to  $v_j$  through  $y$  in  $B_j$  having a SDR  $S_j$  of the  $P_j$ -bridges in  $B_j$ , such that  $y \notin S_j$ . For  $j < i \leq k$ , let  $P_i$  be a Tutte path in  $B_i$  from  $v_{i-1}$  to  $v_i$  having a SDR  $S_i$  of the  $P_i$ -bridges in  $B_i$ , such that  $v_{i-1} \notin S_i$ .

The cycle obtained by adding  $x, xu$  and  $xv$  to the path  $P_1 \cup P_2 \cup \dots \cup P_k$  is the desired Tutte cycle and  $S = \bigcup_{i=1}^k S_i$  is the required SDR.  $\square$

#### 4. PROOF OF THEOREMS 1 AND 2

In this section we use Theorem 4 to prove Theorems 1 and 2 for circuit graphs. If  $(G, C)$  is a circuit graph, an *internal  $k$ -cut* of  $G$  is a  $k$ -cut  $A$  of  $G$  such that  $G - A$  contains a component disjoint from  $C$ .

**Theorem 6.** *Let  $(G, C)$  be a circuit graph and let  $x, y \in V(C)$ . Then there is a closed 2-walk  $W$  in  $G$  visiting  $x$  and  $y$  only once each such that any vertex visited twice by  $W$  is in either a 2-cut or an internal 3-cut of  $G$ .*

*Proof.* In fact, we shall prove something slightly stronger. We shall require that if  $v$  is a vertex of  $G$  visited twice by  $W$ , then either  $v$  is in an internal 3-cut or there is a 2-cut  $\{v, w\}$  of  $G$  with  $v$  and  $w$  both in the same path in  $C$  from  $x$  to  $y$ , i.e. either both are in  $xCy$  or both are in  $yCx$ .

We proceed by induction on  $|E(G)|$ , with the case  $|E(G)| = 3$  being trivial. For the inductive step, we can suppose that  $G$  is drawn in the plane so that  $C$  bounds the infinite face.

By Corollary 5,  $G$  has a Tutte cycle  $T$  through  $x$  and  $y$  and a SDR  $S$  for the  $T$ -bridges of  $G$  with  $x, y \notin S$ . We use this to construct the desired closed 2-walk.

Let  $L$  be a  $T$ -bridge and let  $s$  be the representative of  $L$  in  $S$ . If  $L$  has only two vertices of attachment, then  $L$  contains an edge of  $C$  (as otherwise  $(G, C)$  is not a circuit graph). The only other possibility is that  $L$  has exactly 3 vertices of attachment.

Suppose first that  $L$  has exactly two vertices of attachment, say  $s$  and  $s'$ . Let  $sCs'$  denote the path  $C \cap L$  and let  $t$  be the neighbour of  $s'$  in  $sCs'$ . By Lemma 3 (2),  $L - s'$  is a plane chain of blocks  $B_1, B_2, \dots, B_m$ , with  $s \in V(B_1)$ ,  $s \notin V(B_2)$ ,  $t \in V(B_m)$  and  $t \notin V(B_{m-1})$ . For  $i = 1, 2, \dots, m - 1$ , let  $v_i$  be the vertex common to  $B_i$  and  $B_{i+1}$  and let  $v_0 = s$ ,  $v_m = t$ .

For  $i = 1, 2, \dots, m$ , either  $B_i$  is just the edge  $v_{i-1}v_i$  and its ends or  $C_i$  is a cycle bounding the infinite face of  $B_i$  and  $(B_i, C_i)$  is a circuit graph. Moreover,  $C_i \cap C$  is a path.

In the first case, we let  $W_i = (v_{i-1}, v_{i-1}v_i, v_i, v_i v_{i-1}, v_{i-1})$ . In the second case, inductively, there is a closed 2-walk  $W_i$  in  $B_i$  visiting each of  $v_{i-1}$  and  $v_i$  only once such that any vertex visited twice by  $W$  is in either a 2-cut of  $B_i$  or an internal 3-cut of  $B_i$ .

Now suppose  $L$  has three vertices of attachment, say  $s$ ,  $s'$  and  $s''$ . Then  $L$  is disjoint from  $C$  except possibly for vertices of attachment. We claim that  $L - \{s', s''\}$  is a plane chain of blocks  $B_1, B_2, \dots, B_m$ , with  $s \in B_1$ ,  $s \notin B_2$ . We can add the edges  $ss', ss'', s's''$  to  $L$  to create a circuit graph  $(L', C')$ , where  $C'$  is the triangle through the new edges and  $L'$  is  $L$  with the three new edges. Deleting  $s'$  yields, by Lemma 3 (2), a plane chain of blocks with  $s$  in one leaf block and  $s''$  in the other. Since they are adjacent, there is only one block. Therefore,  $L' - s'$  is 2-connected and now Lemma 3 (2) shows that  $L - \{s', s''\} = L' - \{s', s''\}$  is a plane chain of blocks, as required.

There is a vertex  $v_m$  in  $B_m$  that is in a face boundary of  $G$  with both  $s'$  and  $s''$ . We proceed exactly as in the case  $L$  has only two vertices of attachment.

It is important to observe that any internal 3-cut of  $B_i$  is an internal 3-cut of  $G$  and the 2-cuts of  $B_i$  that we need to consider (i.e. both vertices in either  $v_{i-1}C_iv_i$  or both vertices in  $v_iC_iv_{i-1}$ ) are either 2-cuts of  $G$  or are contained in internal 3-cuts of  $G$ . It is clear that we can get a closed 2-walk in  $G$  by traversing  $T$  from one representative to the next and then detouring into the bridges using the walks  $W_i$ , being careful to go from  $v_{i-1}$  to  $v_i$  on  $W_i$ , and then going into  $B_{i+1}$  before returning from  $v_i$  to  $v_{i-1}$  on the remainder of  $W_i$ .  $\square$

The appropriate generalization of Theorem 2 to circuit graphs is the following. It follows from Theorem 4 in the same way that Theorem 6 follows from Corollary 5.

**Theorem 7.** *Let  $(G, C)$  be a circuit graph let  $x \in V(C)$  and let  $y \in V(G)$ . Then there is a 2-walk from  $x$  to  $y$  in  $G$  such that any vertex visited twice by  $W$  is in either a 2-cut or an internal 3-cut of  $G$ .*
