# Existence of almost resolvable directed 5-cycle systems 

G. Ge and L. Zhu ${ }^{1}$<br>Department of Mathematics<br>Suzhou University<br>Suzhou, 215006, P.R.China

#### Abstract

A directed $k$-cycle system of order n is a pair ( $\mathrm{S}, \mathrm{T}$ ), where S is an n -set and T is a collection of arc disjoint directed $k$-cycles that partition the complete directed graph $K_{n}{ }^{*}$. An almost parallel class with deficiency $x$ is a set of directed $k$-cycles which form a partition of $\mathrm{S} \backslash\{\mathrm{x}\}$. An almost resolvable directed k -cycle system is a directed k -cycle system in which the cycles can be partitioned into almost parallel classes. It is clear that $n$ $\equiv 1(\bmod \mathrm{k})$ is a necessary condition for the existence of such a system. It is well known that for $k=3$ and 4 the necessary condition is also sufficient. In this paper, we shall introduce a special kind of skew Room frames and discuss their constructions. As an application, we show that an almost resolvable directed 5-cycle system of order $n$ exists if and only if $n \equiv 1(\bmod 5)$.

## 1. Introduction

A directed $k$-cycle system of order n is a pair ( $\mathrm{S}, \mathrm{T}$ ), where S is an n -set and T is a collection of arc disjoint directed $k$-cycles that partition the complete directed graph $\mathrm{K}_{\mathrm{n}}{ }^{*}$. An almost parallel class with deficiency x is a set of directed k -cycles which form a partition of $\mathrm{S} \backslash\{\mathrm{x}\}$. An almost resolvable directed $k$-cycle system of order n , denoted by $\operatorname{ARDkCS}(\mathrm{n})$, is a directed k -cycle system of order n in which the cycles can be partitioned into almost parallel classes. Simple counting shows that

$$
\begin{equation*}
\mathrm{n} \equiv 1(\bmod k) \tag{1}
\end{equation*}
$$

is a necessary condition for the existence of such a system. It has been shown that the necessary condition (1) is also sufficient in the case when $k=3$ by Bennett and Sotteau [1] and in the case when $k=4$ by Bennett and Zhang [2]. In this paper, we shall introduce a special kind of skew Room frames and discuss their constructions. As an application, we shall show that an almost resolvable directed 5 -cycle system of order $n$ exists if and only if $n \equiv 1(\bmod 5)$. This complements the result of Heinrich, Lindner and Rodger [7] which completely settles the existence of almost resolvable (undirected) m-cycle systems for all odd m .

[^0]For general background on Room frames and cycle systems, the reader is referred to the recent surveys by Dinitz and Stinson [5] and by Lindner and Rodger [8].

## 2. Strong skew Room frames and their application to ARDkCS

In this section we shall define a special class of skew Room frames called strong skew Room frames. These Room frames will be used to construct almost resolvable directed k-cycle systems for odd $k$.

Let $S$ be a finite set, and let $\left\{S_{1}, S_{2}, \ldots, S_{n}\right\}$ be a partition of $S$. An $\left\{S_{1}, S_{2}, \ldots, S_{n}\right\}$-Room frame is an $|\mathrm{S}| \times|\mathrm{S}|$ array, F , indexed by S , which satisfies the following properties:

1. Every cell of $F$ either is empty or contains an unordered pair of symbols of $S$.
2. The subarrays $\mathrm{S}_{\mathrm{i}} \times \mathrm{S}_{\mathrm{i}}$ are empty, for $1 \leq \mathrm{i} \leq \mathrm{n}$ ( these subarrays are referred to as holes).
3. Each symbol $x \notin S_{i}$ occurs once in row (or column) $s$, for any $s \in S_{i}$.
4. The pairs in $F$ are those $\{s, t\}$, where $(s, t) \in(S \times S) \backslash \cup_{1 \leq i \leq n}\left(S_{i} \times S_{i}\right)$.

As is usually done in the literature, we shall refer to a Room frame simply as a frame. The type of the frame is defined to be the multiset $\left\{\left|\mathrm{S}_{\mathrm{i}}\right|: 1 \leq \mathrm{i} \leq \mathrm{n}\right\}$. We usually use an "exponential" notation to describe types: a type $t_{1} u_{1} t_{2} u_{2} \ldots t_{k} u_{k}$ denotes $u_{i}$ occurrences of $t_{i}, l \leq i \leq k$. We briefly denote a frame of type $\mathrm{t}_{1} \mathrm{u}_{1} \mathrm{t}_{2} \mathrm{u}_{2} \ldots \mathrm{t}_{\mathrm{k}} \mathrm{u}_{\mathrm{k}}$ by $\operatorname{RF}\left(\mathrm{t}_{1} \mathrm{u}_{1} \mathrm{t}_{2} \mathrm{u}_{2} \ldots \mathrm{t}_{\mathrm{k}} \mathrm{u}_{\mathrm{k}}\right)$.

An $\left\{S_{1}, S_{2}, \ldots, S_{n}\right\}$-Room frame $F$ is called skew if, given any cell $(s, t) \in(S \times S) \backslash$ $\cup_{1 \leq i \leq n}\left(S_{i} \times S_{i}\right)$, precisely one of $(s, t)$ and $(t, s)$ is empty. A skew $R F\left(t_{1} u_{1} t_{2} u_{2} \ldots t_{k} u_{k}\right)$ is denoted by $\operatorname{SRF}\left(\mathrm{t}_{1} \mathrm{u}_{1} \mathrm{t}_{2} \mathrm{u}_{2} \ldots \mathrm{t}_{\mathrm{k}} \mathrm{u}_{\mathrm{k}}\right)$.

A skew Room frame $F$, based on $S$, is called strong if each unordered pair $\{x, y\}$ in $F$ can be replaced either by $(x, y)$ or by $(y, x)$ such that if an ordered pair $(a, b)$ appears in row $r$, then $r$ must appear in F as the second element in column a and as the first element in column b .

A strong skew Room frame of type T will be denoted by $\operatorname{SSRF}(\mathrm{T})$.

Example 2.1 Let $S=\{0,1, \ldots, 6\}$, and let $S_{i}=\{i\}$. An $\operatorname{SSRF}\left(1^{7}\right)$ is shown in Fig. 2.1, where all the pairs are considered as ordered pairs. But the $\operatorname{SRF}\left(1^{7}\right)$ in Fig. 2.2 is not strong. For, if we take an ordered pair $(1,5)$ in row 0 and column 3 , then the pair $\{0,2\}$ is forced to become an ordered pair ( 2,0 ) in row 3. From the latter we further get an ordered pair (3,4) in row 1, which contradicts the first pair. If we take the ordered pair ( 5,1 ), the situation is similar.

Fig. 2.2 An $\operatorname{SRF}\left(1^{7}\right)$ which is not strong

In order to use strong skew Room frames to construct almost resolvable directed k-cycle systems for odd $k$ we need two sequences as follows (see also [7]). For $0 \leq i \leq[k / 2]$, define

$$
\begin{aligned}
& e_{i}=(-1)^{i+1}[(i+1) / 2](\bmod k) \\
& d_{i}=[k / 2]+1+(-1)^{i}[(i+1) / 2](\bmod k)
\end{aligned}
$$

Lemma 2.2 The sequences $\left(d_{0}, d_{1}, \ldots, d_{[k / 2]}\right)$ and $\left(e_{0}, e_{1}, \ldots, e_{[k / 2]}\right)$ satisfy the following properties:
(1) $\left\{\left|\mathrm{d}_{\mathrm{i}}-\mathrm{d}_{\mathrm{i} \cdot 1}\right|_{\mathrm{k}} \mid \mathrm{l} \leq \mathrm{i} \leq[\mathrm{k} / 2]\right\}=\{\mathrm{i} \mid 1 \leq \mathrm{i} \leq[\mathrm{k} / 2]\}$,
(2) $d_{i}-d_{i-1}=e_{i-1}-e_{i}$ for $1 \leq i \leq[k / 2]$,
(3) $d_{[k / 2]}=e_{[k / 2]}$,
(4) $\left\{\mathrm{d}_{0}, \mathrm{~d}_{1}, \ldots, \mathrm{~d}_{[\mathrm{k} / 2]}, \mathrm{e}_{0}, \mathrm{e}_{1}, \ldots, \mathrm{e}_{[\mathrm{k} / 2]}\right\}=\{\mathrm{i} \mid 0 \leq \mathrm{i} \leq \mathrm{k}-1\}$,
where $|\mathrm{i}-\mathrm{j}|_{\mathrm{k}}$ is defined to be a positive integer x such that $\mathrm{x} \leq[\mathrm{k} / 2]$ and $\mathrm{x} \equiv \mathrm{i}-\mathrm{j}(\bmod \mathrm{k})$ or $\mathrm{x} \equiv$ $j-i(\bmod k)$.

The following construction is a slightly revised version of The Skew Room Frame Construction in [7], adapted here for the directed case.

Construction 2.3 Suppose there exist an $\operatorname{SSRF}\left(\mathrm{h}^{\mathrm{u}}\right)$ and an $\operatorname{ARDkCS}(\mathrm{hk}+1)$ for odd k . Then there exists an $\operatorname{ARDkCS}($ huk +1 ).

Proof: Let the given $\operatorname{SSRF}\left(\mathrm{h}^{\mathrm{u}}\right) \mathrm{F}$ be based on S with partition $\left\{\mathrm{S}_{1}, \mathrm{~S}_{2}, \ldots, \mathrm{~S}_{\mathrm{u}}\right\}$. Let $\mathrm{K}=\{0,1, \ldots$, $k-1\}$. We shall construct an $\operatorname{ARDkCS}(h u k+1)$ on $X=\{\infty\} \cup(S \times K)$. In this construction, all additions are defined modulo $k$. Define a collection of directed $k$-cycles $\mathbf{C}$ as follows:
(1) for each $\mathrm{S}_{\mathrm{i}}, 1 \leq \mathrm{i} \leq u$, define an $\operatorname{ARDkCS}(\mathrm{hk}+1)$ on the set $\{\infty\} \cup\left(\mathrm{S}_{\mathrm{i}} \times \mathrm{K}\right)$ and place these directed k -cycles in C ;
(2) for each pair ( $x, y$ ) of row $r$ and column $c$ in $F$ and for each $j, 0 \leq j \leq k-1$, place in $C$ two directed k-cycles:

$$
\begin{aligned}
& \quad(x, y, r, d, j)=\left(\left(x, d_{0}+j\right), \ldots,\left(y, d_{2 t}+j\right),\left(r, d_{2 t+1}+j\right),\left(x, d_{2 t}+j\right), \ldots,\left(y, d_{0}+j\right)\right) \text { and } \\
& \quad(y, x, c, e, j)=\left(\left(y, e_{0}+j\right), \ldots,\left(x, e_{2 t}+j\right),\left(c, e_{2 t+1}+j\right),\left(y, e_{2 t}+j\right), \ldots,\left(x, e_{0}+j\right)\right) \text { if } k=4 t+3 \\
& \text { or }(x, y, r, d, j)=\left(\left(x, d_{0}+j\right), \ldots,\left(x, d_{2 t-1}+j\right),\left(r, d_{2 t}+j\right),\left(y, d_{2 t-1}+j\right), \ldots,\left(y, d_{0}+j\right)\right) \text { and } \\
& (y, x, c, e, j)=\left(\left(y, e_{0}+j\right), \ldots,\left(y, e_{2 t-1}+j\right),\left(c, e_{2 t}+j\right),\left(x, e_{2 t-1}+j\right), \ldots,\left(x, e_{0}+j\right)\right) \text { if } k=4 t+1 .
\end{aligned}
$$

We need to show that ( $X, C$ ) is a directed $k$-cycle system and also it is almost resolvable. We shall focus on the case when $k=4 t+3$, the case when $k=4 t+1$ can be proved similarly.

To see that ( $\mathrm{X}, \mathrm{C}$ ) is a directed $k$-cycle system, we need only to show, by simple counting argument, that any arc of $\mathrm{K}_{\mathrm{n}}^{*}, \mathrm{n}=$ huk +1 , is contained in at least one directed k -cycle of C . For
any $\operatorname{arc}(\alpha, \beta)$ of $K_{n}{ }^{*}$, if $\alpha=\infty$ or $\beta=\infty$, then by (1) the arc appears in some directed $k$-cycle of C. If the first coordinates of $\alpha$ and $\beta$ are in the same set $S_{i}$ for some $i$, then by (1) the arc also appears in some directed $k$-cycle of $C$. Otherwise, we may suppose $\alpha=(\mathrm{a}, \mathrm{p}), \beta=(\mathrm{b}, \mathrm{q})$ and a and $b$ belong to different $S_{i}$. In the following case 1 and case 2 , without loss of generality, we further suppose that the ordered pair ( $a, b$ ) appears in row $r$ and column $c$ of $F$.

Case 1. When $q=p$, there is a unique $j$ such that $p=e_{0}+j$. Then there is a directed $k$-cycle ( $b, a, c, e, j$ ) in $C$ containing the given arc $(\alpha, \beta)$.

Case 2. When $|\mathrm{q}-\mathrm{p}|_{\mathrm{k}} \notin\left\{0,\left|\mathrm{~d}_{2 \mathrm{t}+1}-\mathrm{d}_{2 \mathrm{t}}\right|_{\mathrm{k}}\right\}$, by property (1) in Lemma 2.2 there is a unique i such that $|q-p|_{k}=\left|d_{i}-d_{i-1}\right|_{k}$. By property (2) in Lemma 2.2 we have $|q-p|_{k}=\left|e_{i}-e_{i-1}\right|_{k}$. If $i$ is even, then there is a unique j such that the directed k -cycle $(\mathrm{b}, \mathrm{a}, \mathrm{c}, \mathrm{e}, \mathrm{j})$ in C contains the given $\operatorname{arc}((a, p),(b, q))$, where $j=p-e_{i-1}$ or $p-e_{i}$ according to $q-p=e_{i}-e_{i-1}$ or $e_{i-1}-e_{i}$, respectively. If $i$ is odd, then there is a unique $j$ such that the directed $k$-cycle ( $a, b, r, d, j)$ in $C$ contains the given arc $((a, p),(b, q))$, where $j=p-d_{i-1}$ or $p-d_{i}$ according to $q-p=d_{i}-d_{i-1}$ or $d_{i-1}-d_{i}$, respectively.

Case 3. When $|q-p|_{k}=\mid d_{2 t+1}-d_{2 t_{k}}$, by property (2) in Lemma 2.2 we have $|q-p|_{k}=$ $\mid e_{2 t+1}-e_{2 l} l_{k}$. Since $a$ and $b$ belong to different $S_{i}$, a must appear in row $b$ and $b$ must appear in row a of F . By definition of strong skew Room frame F , we have the following two subcases to consider.

Subcase 3.1 Suppose $q-p=d_{2 t+1}-d_{2 t}=e_{2 t}-e_{2 t+1}$. If a appears in row $b$ as the second element, we may let ( $x$, a ) appears in row $b$ and column $c$ of $F$. Then, there is a directed $k$-cycle ( $x, a, b, d, j$ ) in $C$ containing the given arc $((a, p),(b, q))$, where $j=q-d_{2 t+1}$. If $a$ appears in row $b$ as the first element, since $F$ is strong, $b$ must appear in column $a$ of $F$ as the second element. Let ( $x, b$ ) appears in row $r$ and column a of $F$. Then, there is a directed $k$-cycle $(b, x, a, e, j)$ in $C$ containing the given arc $((a, p),(b, q))$, where $j=q-e_{2 t}$.

Subcase 3.2 Suppose $q-p=e_{2 t+1}-e_{2 t}=d_{2 t}-d_{2 t+1}$. If $b$ appears in row $a$ as the second element, since $F$ is strong, a must appear in column $b$ of $F$ as the first element. Let ( $a, y$ ) appears in row $r$ and column $b$ of $F$. Then, there is a directed $k$-cycle $(y, a, b, e, j)$ in $C$ containing the given $\operatorname{arc}((a, p),(b, q))$, where $j=q-e_{2 t+1}$. If $b$ appears in row $a$ as the first element, we may let ( $b, y$ ) appears in row a and column $c$ of $F$. Then, there is a directed $k$-cycle ( $b, y, a, d, j$ ) in $C$ containing the given $\operatorname{arc}((a, p),(b, q))$, where $j=q-d_{2 t}$.

We have proved that ( $\mathbf{X}, \mathbf{C}$ ) is a directed k -cycle system and we shall now show that it is almost resolvable. For each set $H \in\left\{S_{1}, S_{2}, \ldots, S_{u}\right\}$, denote by $\pi(\infty, H)$ the almost parallel class that has deficiency $\infty$ and by $\pi((x, j), H)$ the almost parallel class with deficiency $(x, j)$ in the resolution of $\operatorname{ARDkCS}(\mathrm{hk}+1)$ on the set $\{\infty\} \cup(\mathrm{H} \times \mathrm{K})$.

For each $w \in\{\infty\} \cup(S \times K)$ define the almost parallel class $\pi(w)$ with deficiency $w$ as follows:
(1) $\pi(\infty)=\cup_{1 \leq i \leq u} \pi\left(\infty, S_{i}\right)$; and
(2) for each $(x, j) \in S \times K$ with $x \in S_{i}$,

$$
\begin{aligned}
\pi((\mathrm{x}, \mathrm{j}))= & \pi\left((\mathrm{x}, \mathrm{j}), \mathrm{S}_{\mathrm{i}}\right) \\
& \cup\{(\mathrm{a}, \mathrm{~b}, \mathrm{r}, \mathrm{~d}, \mathrm{j}) \mid \text { all }(\mathrm{a}, \mathrm{~b}) \text { in column } \mathrm{x} \text { of } \mathrm{F}\} \\
& \cup\{(\mathrm{b}, \mathrm{a}, \mathrm{c}, \mathrm{e}, \mathrm{j}) \mid \text { all }(\mathrm{a}, \mathrm{~b}) \text { in row } \mathrm{x} \text { of } \mathrm{F}\} .
\end{aligned}
$$

Corollary 2.4 Suppose there is an $\operatorname{SSRF}\left(1^{u}\right)$. Then there exists and $\operatorname{ARDkCS}(\mathrm{uk}+1)$ for odd k .

Proof: From [3, Theorem 3], there exists a directed $k$-cycle system of order $k+1$ for any odd $k$, which is also an $\operatorname{ARDkCS}(\mathrm{k}+1)$.Then the conclusion follows from Construction 2.3.

Corollary 2.5 Suppose there is an $\operatorname{SSRF}\left(2^{\mathrm{u}}\right)$. Then there exists and $\operatorname{ARDkCS}(2 u k+1)$ for odd $\mathrm{k} \geq 3$.

Proof: We construct an $\operatorname{ARDkCS}(2 k+1)$ on $Z_{2 k+1}$. Let $k=2 t+1($ so $t \geq 1)$. Let

$$
\mathrm{c}=\left(-1,2,-3, \ldots,(-1)^{\mathrm{t} t},(-1)^{1}(\mathrm{t}+1),(-1)^{)^{t+1}(t+2), \ldots,(-1)^{\mathrm{t}} \mathrm{t},(-1)^{2 \mathrm{t}}(2 \mathrm{t}+1)\right),, ~(t)}\right.
$$

where each component of c is reduced modulo $2 \mathrm{k}+1$. Let -c and $\mathrm{c}+\mathrm{i}$ be formed by replacing each component $\mathrm{c}_{\mathrm{j}}($ for $\mathrm{l} \leq \mathrm{j} \leq \mathrm{k})$ of c by $-\mathrm{c}_{\mathrm{j}}(\bmod 2 \mathrm{k}+1)$ and $\mathrm{c}_{\mathrm{j}}+\mathrm{i}(\bmod 2 \mathrm{k}+1)$, respectively. Then c and -c form an almost parallel class with deficiency 0 and $\mathrm{C}=\{\mathrm{c}+\mathrm{i},-\mathrm{c}+$ $\mathrm{i} \mid 0 \leq i \leq 2 k\}$ is an $\operatorname{ARDkCS}(2 k+1)$. Then the conclusion follows from Construction 2.3.

## 3. Constructions of strong skew Room frames

In this section, we shall discuss constructions of strong skew Room frames. We mainly use the direct constructions for Room frames.

Let G be an additive abelian group of order g , and let H be a subgroup of order h of G , where $\mathrm{g}-\mathrm{h}$ is even. A frame starter in GH is a set of unordered pairs $\mathrm{S}=\left\{\left\{\mathrm{s}_{\mathrm{i}}, \mathrm{t}_{\mathrm{i}}\right\}: 1 \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\right\}$ such that the following two properties are satisfied:

1. $\left\{\mathrm{s}_{\mathrm{i}}: 1 \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\right\} \cup\left\{\mathrm{t}_{\mathrm{i}}: 1 \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\right\}=\mathrm{G} \backslash \mathrm{H}$.
2. $\left\{ \pm\left(\mathrm{s}_{\mathrm{i}}-\mathrm{t}_{\mathrm{i}}\right): 1 \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\right\}=\mathrm{GUH}$.

The type of the frame is defined to be $\mathrm{h}^{\mathrm{gh}}$. When $\mathrm{H}=\{0\}$, a frame starter is simply called a starter. A frame starter $\mathrm{S}=\left\{\left\{\mathrm{s}_{\mathrm{i}}, \mathrm{t}_{\mathrm{i}}\right\}: \mathrm{l} \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\right\}$ in GHH is called skew if $\left\{ \pm\left(\mathrm{s}_{\mathrm{i}}+\mathrm{t}_{\mathrm{i}}\right)\right.$ : $1 \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\}=\mathrm{G} \backslash \mathrm{H}$.

From a skew frame starter, one can construct a skew Room frame easily. For each element $b$ in $G$ and each pair $\{s, t\}$ in a skew starter $S$, place in cell $(b, b+s+t)$ the pair $\{b+s, b+t\}$ to
form a skew Room frame F indexed by G. We can further prove that the skew Room frame is also strong.

Lemma 3.1 If there is a skew frame starter of type $h^{u}$, then there exists an $\operatorname{SSRF}\left(h^{u}\right)$.

Proof: To prove the above-defined skew Room frame F is strong, we need to show that b must appear in column $b+s$ as the second element and in column $b+t$ as the first element in $F$, where the pair $\{b+s, b+t\}$ in $F$ is considered as the ordered pair $(b+s, b+t)$. In fact, $F$ contains $(b+s-t, b)$ in cell $(b-t, b+s)$ and $(b, b+t-s)$ in cell $(b-s, b+t)$. This completes the proof.

For example, the $\operatorname{SSRF}\left(1^{7}\right)$ in Fig. 2.1 is constructed from a skew frame starter $S=\{\{2,6\}$, $\{4,5\},\{1,3\}\}$ in $Z_{7} \backslash\{0\}$. The following known skew frame starters will be useful.

Lemma 3.2 ([10]) Let $n$ be a prime power such that $n=2^{k} t+1$, where $t>1$ is odd. Then there is a skew frame starter of type ( $1^{\mathrm{n}}$ ).

Lemma 3.3 ([9]) There is a skew frame starter of type ( $\mathrm{l}^{\mathrm{n}}$ ) for $\mathrm{n}=16 \mathrm{k}^{2}+1$, where k is any positive integer.

Lemma $3.4([6],[12])$ If $q \equiv 1(\bmod 4)$ is a prime power and $n \geq 1$, then there is a skew frame starter in $\left(\mathrm{GF}(\mathrm{q}) \times\left(\mathrm{Z}_{2}\right)^{\mathrm{n}}\right) \backslash\left(\{0\} \times\left(\mathrm{Z}_{2}\right)^{\mathrm{n}}\right)$.

Lemma 3.5 There are skew frame starters of type (44) and type ( $\left.1^{35}\right)$.

Proof: The first skew frame starter $S$ can be found in [11, Lemma 5.1]. In $\left(Z_{4} \times Z_{4}\right) \backslash\{(0,0)$, $(0,2),(2,0),(2,2)\}, S=\{\{(3,2),(1,1)\},\{(3,0),(3,1)\},\{(2,1),(3,3)\},\{(0,3),(1,3)\}$, $\{(1,0),(2,3)\},\{(1,2),(0,1)\}\}$. The second is shown below, where the starter is in $Z_{35} \backslash\{0\} . S=$ $\{\{1,2\},\{3,5\},\{4,7\},\{6,10\},\{8,15\},\{9,21\},\{11,25\},\{12,29\},\{13,24\},\{14,30\}$, $\{16,26\},\{17,22\},\{18,31\},\{19,34\},\{20,28\},\{23,32\},\{27,33\}\}$.

For some group $G$ there is no skew starter in $G$ as pointed out in the following.

Lemma 3.6 ([13] ) Suppose that $G$ is an abelian group of order $n \equiv 3(\bmod 6)$ in which the 3 Sylow subgroup is cyclic. Then there is no skew starter in G.

For example, $\mathrm{n}=15$ is such an order. But, we can use starter-adder construction to find an $\operatorname{SSRF}\left(1^{15}\right)$. If $\mathrm{S}=\left\{\left\{\mathrm{s}_{\mathrm{i}}, \mathrm{t}_{\mathrm{i}}\right\}: 1 \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\right\}$ is a frame starter in $\mathrm{G} \backslash H$, then a set $\mathrm{A}=\left\{\left\{\mathrm{a}_{\mathrm{i}}\right\}:\right.$ $\mathrm{I} \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\}$ is defined to be an adder for S if the elements in A are distinct in $\mathrm{G} H \mathrm{H}$, and the set $S+A=\left\{\left\{s_{i}+a_{i}, t_{i}+a_{i}\right\}: 1 \leq i \leq(g-h) / 2\right\}$ is again a frame starter. An adder is said to be skew if for any $\mathrm{a} \in \mathrm{A},-\mathrm{a}$ is not in A . It is well known that the existence of a frame starter and a skew adder implies the existence of a skew Room frame with the same type. The frame $F$, indexed by $G$, will contain in cell $\left(b, b-a_{i}\right)$ the pair $\left\{b+s_{i}, b+t_{i}\right\}$ for any $b \in G$.

A frame starter and a skew adder ( $\mathrm{S}, \mathrm{A}$ ) is called strong if $\left\{-\mathrm{s}_{\mathrm{i}}-\mathrm{a}_{\mathrm{i}}: 1 \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\right\}=$ $\left\{t_{j}: 1 \leq j \leq(g-h) / 2\right\}$. Since $S$ and $S+A$ are both frame starters, it is equivalent to $\left\{-t_{i}-a_{i}\right.$ : $1 \leq \mathrm{i} \leq(\mathrm{g}-\mathrm{h}) / 2\}=\left\{\mathrm{s}_{\mathrm{j}}: \mathrm{l} \leq \mathrm{j} \leq(\mathrm{g}-\mathrm{h}) / 2\right\}$.

Lemma 3.7 If there is a frame starter and a skew adder ( $\mathrm{S}, \mathrm{A}$ ) which is strong, then there is a strong skew Room frame with the same type.

Proof: Since the skew frame $F$ contains the ordered pair $\left(b+s_{i}, b+t_{i}\right)$ in cell $\left(b, b-a_{i}\right)$ for any $b$ $\in G$, we know that $\left(b, b+t_{i}-s_{i}\right)$ appears in cell $\left(b-s_{i}, b-a_{i}-s_{i}\right)$. Since $(S, A)$ is strong, there is an integer $j$ such that $b=a_{i}-s_{i}=b+t_{j}$. That is, $b$ appears in column $b+t_{j}$ as the first element in F. Similarly, $b$ appears in column $b-a_{i}-t_{i}=b+s_{j}$, for some $j$, as the second element in $F$. When $i$ and $j$ run through 1 to $(g-h) / 2$, we know that $b$ appears in column $b+s_{i}$ as the second element and in column $b+t_{i}$ as the first element in $F$. Therefore, the skew frame $F$ is strong. The proof is complete.

Lemma 3.8 There exists an $\operatorname{SSRF}\left(1^{15}\right)$.

Proof: Let $\mathrm{G}=\mathrm{Z}_{15}$ and $\mathrm{H}=\{0\}$. Take $\mathrm{S}=\{(1,4),(10,6),(12,13),(11,3),(2,8),(5,7)$, $(9,14)\}$ and $A=\{1,13,12,11,10,6,7\}$. It is readily checked that the frame starter and skew adder ( $\mathrm{S}, \mathrm{A}$ ) is strong. The conclusion then follows from Lemma 3.7.

Lemma 3.9 There exists an $\operatorname{SSRF}\left(2^{8}\right)$.

Proof: Let $G=Z_{16}$ and $H=\{0,8\}$. Take $S=\{(2,5),(7,3),(9,11),(15,14),(10,4)$, $(12,1),(6,13)\}$ and $A=\{1,14,3,12,5,6,7\}$. It is readily checked that the frame starter and skew adder ( $\mathrm{S}, \mathrm{A}$ ) is strong. The conclusion then follows from Lemma 3.7.

## 4. Existence of almost resolvable directed 5-cycle systems

In this section, we shall solve the existence of almost resolvable directed 5-cycle systems. We start with group divisible directed k -cycle systems.

A group divisible directed $k$-cycle system (GDDkCS ) is a triple ( $\mathrm{S}, \mathrm{G}, \mathrm{T}$ ), where G is a partition of the set S and T is a collection of arc disjoint directed k-cycles that partition the complete directed multipartite graph on S with partition $\mathbf{G}$. The group type of the GDDkCS is the multiset $\{|G|: G \in \mathbf{G}\}$. An almost parallel class with deficiency $G$ for $G \in \mathbf{G}$ is a set of directed k -cycles which form a partition of SIG. An almost resolvable group divisible directed $k$-cycle system (ARGDDkCS ) is a GDDkCS in which the cycles can be partitioned into almost parallel classes such that for each group $G \in G$ there are exactly $|G|$ almost parallel classes with deficiency $G$.

We wish to remark that an $\operatorname{ARGDDkCS}$ of type $1^{\mathrm{n}}$ is just an $\operatorname{ARDkCS}(\mathrm{n})$. By Construction 2.3 we can get an ARGDDkCS from an SSRF.

Lemma 4.1 If there exists an $\operatorname{SSRF}\left(\mathrm{h}^{\mathbf{u}}\right)$, then for any odd integer $k \geq 3$, there exists an ARGDDkCS of type (hk) ${ }^{\mathbf{u}}$.

To get an ARDkCS from an ARGDDkCS and some ARDkCS we have the following obvious filling-in-holes construction.

Lemma 4.2 If there exists an $\operatorname{ARGDDkCS}(S, G, T)$ and if for any $G$ in $G$ there exists an $\operatorname{ARDkCS}(|G|+1)$, then there exists an $\operatorname{ARDkCS}(|S|+1)$.

We shall further use group divisible designs to construct ARGDDkCS and ARDkCS. A group divisible design (or GDD), is a triple ( $\mathrm{X}, \mathrm{G}, \mathbf{B}$ ) which satisfies the following properties:
(1) G is a partition of X into subsets called groups,
(2) B is a set of subsets of $X$ (called blocks) such that a group and a block contain at most one common point,
(3) every pair of points from distinct groups occurs in a unique block.

The group type of the GDD is the multiset $\{|G|: G \in G\}$. A TD $(k, n)$ is a GDD of group type $n^{k}$ and block size $k$. It is well known that the existence of a $\operatorname{TD}(k, n)$ is equivalent to the existence of $k$ - 2 mutually orthogonal Latin squares (MOLS ) of order $n$ and also to the existence of resolvable TD(k-1, n). For more about TD and MOLS the reader is referred to Beth, Jungnickel and Lenz [4]. We have the following two weighting construction.

Construction 4.3 Suppose ( $\mathbf{S}, \mathbf{G}, \mathbf{B}$ ) is a GDD and let $\mathbf{w}: \mathbf{X} \rightarrow \mathbf{Z}^{+} \cup\{0\}$. Suppose there exists an ARGDDkCS of type $\{\mathrm{w}(\mathrm{x}): \mathrm{x} \in \mathrm{B}\}$ for every $\mathrm{B} \in \mathbf{B}$. Then there exists an ARGDDkCS of type $\left\{\Sigma_{\mathrm{x} \in \mathrm{G}} \mathrm{w}(\mathrm{x}): \mathbf{G} \in \mathbf{G}\right\}$.

Proof: The resultant system will be based on $\mathbb{S}^{*}=\cup_{x \in S} S_{x}$, where for $x \in S, S_{x}$ are pairwise disjoint and $\left|S_{x}\right|=w(x)$. The new partition of $S^{*}$ will be $G^{*}=\left\{\cup_{x \in G} S_{x}: G \in G\right\}$. Suppose $\mathbf{A}_{\mathbf{B}}$ is the set of cycles for an ARGDDkCS of type $\{\mathrm{w}(\mathrm{x}): \mathrm{x} \in \mathrm{B}\}, \mathrm{B} \in \mathbf{B}$. Then, $\mathbf{B}^{*}=$ $\cup_{B \in \mathbf{B}} \mathbf{A}_{\mathrm{B}}$ is the set of cycles for the ARGDDkCS. For any x in certain G , let $\mathbf{B}_{\mathrm{x}}$ consists of all blocks in B containing x . Let $\mathrm{P}(\mathrm{x}, \mathrm{B}, \mathrm{j})$ denote the j -th almost parallel class with deficiency $\mathrm{S}_{\mathrm{x}}$, $1 \leq j \leq w(x)$, in the ARGDDkCS of type $\{w(x): x \in B\}$ for $B \in B_{x}$. Then $P(x, j)=\cup_{B}$ $P(x, B, j)$, where $B$ runs over $B_{X}$, is an almost parallel class with deficiency $\cup_{x \in G} S_{x}$. For each $G \in G$, there are all together $\Sigma_{X \in G} w(x)$ almost parallel classes with deficiency $\cup_{x \in G} S_{X}$. This completes the proof.

Construction 4.4 Suppose ( $\mathrm{S}, \mathrm{G}, \mathrm{T}$ ) is an ARGDDkCS of type T. If there exists a resolvable $\mathrm{TD}(3, \mathrm{~m})$, then there exists an ARGDDkCS of type $\mathrm{mT}=\{\mathrm{mt}: \mathrm{t} \in \mathrm{T}\}$.

Proof: Let $\mathrm{M}=\{1,2, \ldots, \mathrm{~m}\}$ and let the $\operatorname{TD}(3, \mathrm{~m})$ be based on $\mathrm{M} \times\{1,2,3\}$ having three groups $M \times\{j\}, 1 \leq j \leq 3$. For each cycle $c=\left(c_{1}, c_{2}, \ldots, c_{k}\right)$ in $T$ and each block $B=\{(x, 1),(y, 2)$, $(\mathrm{z}, 3)\}$ in the $\mathrm{TD}(3, \mathrm{~m})$, define a directed k -cycle $\mathrm{c} \times \mathrm{B}=\left(\left(\mathrm{c}_{1}, \mathrm{x}\right),\left(\mathrm{c}_{2}, \mathrm{y}\right), \ldots,\left(\mathrm{c}_{\mathrm{k}-2}, \mathrm{x}\right),\left(\mathrm{c}_{\mathrm{k}-1}, \mathrm{y}\right)\right.$, $\left(c_{k}, z\right)$ ). All these cycles will form the set of cycles for the resultant ARGDDkCS, which will be based on the set $S \times M$ having the partition $\{G \times M: G \in G\}$. Let $P(G, j)$ be the $j$-th almost parallel class of the given ARGDDkCS with deficiency $\mathrm{G}, \mathrm{l} \leq \mathrm{j} \leq|\mathrm{G}|$. Let $\mathrm{Q}(\mathrm{i})$ be the i -th parallel class of the resolvable $\operatorname{TD}(3, m)$. Denote $P(G, j, i)=\{c \times B: c \in P(G, j), B \in Q(i)\}$. Then $P(G, j, i)$ is an almost parallel class with deficiency $G \times M$ and there are $m|G|$ such almost parallel classes. This completes the proof.

We are now in a position to show the existence of an $\operatorname{ARD5CS}(\mathrm{n})$. First, from the proof of Corollary 2.4 and Corollary 2.5 we have $\operatorname{ARD5CS}(\mathrm{n})$ for $\mathrm{n}=6$ and 11 .

Lemma 4.5 For any odd integer $k \geq 3$, there are $\operatorname{ARDkCS}(k+1)$ and $\operatorname{ARDkCS}(2 k+1)$.

Lemma 4.6 For any prime power $q \equiv 1(\bmod k)$, there exists an $\operatorname{ARDkCS}(q)$.

Proof: Let x be a primitive element of $\mathrm{GF}(\mathrm{q})$. Let $\mathrm{y}=\mathrm{x}^{\mathrm{d}}, \mathrm{d}=(\mathrm{q}-1) / \mathrm{k}$. Denote $\mathrm{B}(\mathrm{i}, \mathrm{g})=$ $\left(x^{i} y^{1}+g, x^{i} y^{2}+g, \ldots, x^{i} y^{k}+g\right)$ and $B=\{B(i, g): 1 \leq i \leq d$ and $g \in \operatorname{GF}(q)\}$. Then, $(\operatorname{GF}(q)$,
$B)$ is the desired $\operatorname{ARDkCS}(q)$ where for each $g \in \operatorname{GF}(q),\{B(i, g): 1 \leq i \leq d\}$ is the almost parallel class with deficiency $g$.

Lemma 4.7 There exist ARGDD5CS of type $5^{u}$ for $u=5,6,7$ and 9 .

Proof: There is an $\operatorname{ARDkCS}(6)$ from Lemma 4.5, which is also an ARGDD5CS of type $1^{6}$. Applying Construction 4.4 with $\mathrm{k}=5$ we obtain an ARGDD5CS of type $5^{6}$. An $\operatorname{SSRF}\left(1^{7}\right)$ exists from Lemma 3.2, which leads to an ARGDD5CS of type $5^{7}$ by Lemma 4.1. An ARGDD5CS of type $5^{5}(S, G, T)$ is shown below, where $S=Z_{25}$ and $G=\{\{0,5,10,15,20\}+\mathrm{i}: 0 \leq \mathrm{i} \leq 4\}$. T is generated modulo 25 by the following initial directed cycles: ( $1,3,17,21,13$ ), ( $2,14,11,7$, $16),(4,12,19,22,23),(6,24,18,9,8)$, which form an almost parallel class with deficiency 0 . For type $5^{9}$, take $\mathrm{S}=\mathrm{Z}_{45}$ and $\mathrm{G}=\{\{0,9,18,27,36\}+\mathrm{i}: 0 \leq \mathrm{i} \leq 8\}$. The initial directed cycles are:

$$
\begin{aligned}
& (1,3,13,5,8),(2,32,10,11,26),(4,23,37,41,21),(6,38,15,39,44) \\
& (7,19,25,33,17),(12,29,40,35,24), \\
& (14,34,31,30,43), \\
& (16,42,28,22,20)
\end{aligned}
$$

These cycles form an almost parallel class with deficiency 0 .

Lemma 4.8 There exists an ARD5CS of order 21.

Proof: Let $\mathrm{S}=\mathrm{Z}_{20} \cup\{\infty\}$. Four directed cycles $(0,4,8,12,16)+\mathrm{i}$ for $0 \leq \mathrm{i} \leq 3$ form an almost parallel class with deficiency $\infty$. For any $g \in Z_{20}$, the following four cycles form an almost parallel class with deficiency $g:(2,7,10,17,8)+g,(3,13,19,18,11)+g,(4,6,14,12,9)$ $+\mathrm{g},(15,16,5,1, \infty)+\mathrm{g}$. Let T denote the set of all these cycles. Then, (S,T) is the desired ARD5CS(21).

Lemma 4.9 For any integer $v, 1 \leq v \leq 9$, there exists an $\operatorname{ARD5CS}(5 v+1)$.

Proof: For $v=1,2$ and 4, an ARD5CS( $5 v+1)$ exists by Lemmas 4.5 and 4.8. For $v=5,6,7$ and 9, an ARD5CS( $5 v+1$ ) exists by Lemmas 4.7 and 4.2. Finally, Lemma 4.6 takes care of the cases $\mathrm{v}=3$ and 8 .

Lemma 4.10 For any integer $v, 10 \leq v \leq 24$, there exists an $\operatorname{ARD} 5 \operatorname{CS}(5 v+1)$.

Proof: We shall deal with these cases in Table 4.1.

| 24 | 121 | Lemma 4.6 |  |

## Table 4.1

Lemma 4.11 For any integer $v, 25 \leq v \leq 30$, there exists an $\operatorname{ARD} 5 \operatorname{CS}(5 v+1)$.

Proof: Start with a TD $(6,5)$, which exists from [4], and give weight 5 to each point of the TD except 5 - a points in some group, for which we give weight 0 each. Applying Construction 4.3 with ARGDD5CS of type $5^{5}$ and $5^{6}$, we obtain an ARGDD5CS of type $25^{5}(5 \mathrm{a})^{1}$ for $0 \leq \mathrm{a} \leq 5$. The conclusion then follows from Lemma 4.2 and Lemma 4.9.

Lemma 4.12 For any integer $v, 31 \leq v \leq 34$, there exists an $\operatorname{ARD5CS}(5 v+1)$.

Proof: We shall deal with these cases in Table 4.2.

| V | $5 v+1$ | Authority | Ingredients |
| :---: | :---: | :---: | :---: |
| 31 | 156 | Corollary 2.4 | $\operatorname{SSRF}\left(1^{31}\right)$, Lemma 3.2 |
| 32 | 161 | Lemma 4.2 | Apply Construction 4.4 with $T=1^{16}$ and $m=10$ to get an ARGDD5CS of type $10^{16}$ |
| 33 | 166 | Lemma 4.2 | Apply Construction 4.4 with $\mathrm{T}=5^{11}$ and $\mathrm{m}=3$ to get an ARGDD5CS of type $15^{11}$ |
| 34 | 171 | Corollary 2.5 | $\operatorname{SSRF}\left(2^{17}\right)$, Lemma 3.4 |

## Table 4.2

Lemma 4.13 Suppose there exist a $\operatorname{TD}(7, t)$ and an $\operatorname{ARD} 5 \operatorname{CS}(5 v+1)$ for $v=t$, $a$ and $b$, where $0 \leq \mathrm{a}, \mathrm{b} \leq \mathrm{t}$. Then, there exists an $\operatorname{ARD} 5 \operatorname{CS}(5(5 \mathrm{t}+\mathrm{a}+\mathrm{b})+1)$.

Proof: Delete $t$ - a points from one group and $t$ - b points from another group of the TD. Give weight 5 to each point of the resultant GDD. Applying Construction 4.3 gives an ARGDD5CS of type $(5 \mathrm{t})^{5}(5 \mathrm{a})^{1}(5 \mathrm{~b})^{1}$. The input ARGDD5CS of types $5^{5}, 5^{6}$ and $5^{7}$ are all from Lemma 4.7. Further apply Lemma 4.2, we get the desired ARD5CS $(5(5 t+a+b)+1)$.

Lemma 4.14 For any integer $\mathrm{v} \geq 35$, there exists an $\operatorname{ARD5CS}(5 v+1)$.

Proof: We shall prove this Lemma by induction using Lemma 4.13. For any $\mathrm{v} \geq 35$, we may write $v=5 t+a+b$ such that $0 \leq a, b \leq t$ and a TD $(7, t)$ exists. For example, if $v \geq 265$, we may write $v=5 t+a+b$ such that $t$ is odd $\geq 53$ and $0 \leq a, b \leq 5 . A \operatorname{TD}(7, t)$ exists from [4]. Other values of $\mathrm{v}=5 \mathrm{t}+\mathrm{a}+\mathrm{b}$ are given in Table 4.3, where a $\operatorname{TD}(7, \mathrm{t})$ exists from [4].

$$
\begin{array}{lll}
35 \leq v \leq 44, & t=7, & 0 \leq a, b \leq 5, \\
45 \leq v \leq 54, & t=9, & 0 \leq a, b \leq 5, \\
55 \leq v \leq 64, & t=11, & 0 \leq a, b \leq 5, \\
65 \leq v \leq 84, & t=13, & 0 \leq a, b \leq 10, \\
85 \leq v \leq 114, & t=17, & 0 \leq a, b \leq 15, \\
115 \leq v \leq 144, & t=23, & 0 \leq a, b \leq 15, \\
145 \leq v \leq 184, & t=29, & 0 \leq a, b \leq 20, \\
185 \leq v \leq 204, & t=37, & 0 \leq a, b \leq 10, \\
205 \leq v \leq 264, & t=41, & 0 \leq a, b \leq 30,
\end{array}
$$

Table 4.3

By induction hypothesis, an $\operatorname{ARD} 5 \operatorname{CS}(5 t+1)$ exists. Since an $\operatorname{ARD} 5 C S(5 v+1)$ exists for $v \leq 34$, by Lemma 4.13 there exists an $\operatorname{ARDSCS}(5 v+1)$ for $v \geq 35$.

Combining Lemmas 4.9-4.12 and 4.14 we obtain the main theorem of this paper.

Theorem 4.15 There exists an $\operatorname{ARD5CS}(n)$ if and only if $n \equiv 1(\bmod 5)$ and $n \geq 6$.

## 5. Concluding remarks

The existence problem for $\operatorname{ARDkCS}(\mathrm{n})$ has been solved for $\mathrm{k}=3,4$ in [1], [2] and for $\mathrm{k}=5$ in this paper. But, for general $k$ the problem is still open. The new concept of strong skew Room frames and their constructions, introduced and discussed in Sections 2 and 3, are useful in dealing with such a general problem. Especially, the existence problems for $\operatorname{SSRF}\left(1^{\mathrm{n}}\right)$ and $\operatorname{SSRF}\left(2^{\mathrm{n}}\right)$ are very much desirable. However, both of them are again open problems.
