Abstract: A graph is ( $\mathrm{m}, \mathrm{k}$ ) -colourable if its vertices can be coloured with m colours such that the maximum degree of the subgraph induced on vertices receiving the same colour is at most $k$. The $k$-defective chromatic number $\chi_{k}(G)$ of a graph $G$ is the least positive integer $m$ for which $G$ is $(m, k)$-colourable. In this paper we obtain bounds for $\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}})$ and $\chi_{1}(\mathrm{G}) \cdot \chi_{1}(\overline{\mathrm{G}})$ when G ranges over the class of all triangle-free graphs of order $p$.

## 1. Introduction

All graphs considered in this paper are undirected, finite, loopless and have no multiple edges. For the most part we follow the notation of Chartrand and Lesniak [5]. For a graph $G$, we denote the vertex set and the edge set of $G$ by $V(G)$ and $E(G)$ respectively. The complement of a graph $G$ is denoted by $\bar{G}$ and the size of $G$ is denoted by $\varepsilon(G)$. For a positive integer $n, P_{n}$ is a path of order $n$ and $C_{n}$ is a cycle of order $n$. For a subset $U$ of $V(G)$, the subgraph of $G$ induced on $U$ is denoted by $G[\mathrm{U}]$ and the subgraph induced on $\mathrm{V}(\mathrm{G})-\mathrm{U}$ is denoted by $\mathrm{G}-\mathrm{U}$.

Let $G$ be a graph and $X$ a subset of $V(G)$. For a vertex $u$ of $G$, let $N(u)$ denote the set of all neighbours of $u$ in $G$ and let $N_{X}(u)=N(u) \cap X$. Let $N[u]$ denote the closed neighbourhood of $u$, that is, $N(u) \cup\{u\}$. A graph $G$ is said to have the property $t P_{3}$ if the maximum number of vertex disjoint paths of order 3 in $G$ is $t$. $G$ is said to have the property $\mathrm{D}(1, s)$ if G has a $\mathrm{C}_{4}$ and s vertex disjoint paths of order 3 each, such that the vertex set of the $\mathrm{C}_{4}$ is disjoint from the vertices of the $s$ paths of

[^0]order 3.
Let $F$ be a graph. A graph $G$ is said to be $F$-free, if it does not contain $F$ as an induced subgraph. A graph is said to be triangle-free if it is $K_{3}$-free. The generalized Ramsey number $R(K(1, m), K(1, n))$ is the least positive integer $p$ such that for every graph $G$ of order $p$ either $G$ contains $K(1, m)$ as a subgraph or $\bar{G}$ contains $K(1, n)$ as a subgraph. We extend this definition to the class of triangle-free graphs. For positive integers $m$ and $n$, we define $R^{\prime}(K(1, m), K(1, n))$ as the least positive integer $p$ such that if $G$ is a triangle-free graph of order $p$ either $G$ contains $K(1, m)$ as a subgraph or $\bar{G}$ contains $K(1, n)$ as a subgraph. It is easy to see that
$$
R^{\prime}(K(1, m), K(1, n)) \leq R(K(1, m), K(1, n))=R(K(1, n), K(1, m))
$$

A subset $U$ of $V(G)$ is said to be $k$-independent if the maximum degree of $G[U]$ is at most $k$ and $U$ is said to be maximal $k$-independent if $U$ is $k$-independent and $U \cup$ $\{x\}$ is not a k-independent set for any $x \in V(G)-U$. The size of a largest $k$ independent set of $G$ is called the $k$-independence number of $G$ and is denoted by $\alpha_{k}(G)$.

A graph is $(\mathbf{m}, \mathbf{k})$-colourable if its vertices can be coloured with $m$ colours such that the subgraph induced on vertices receiving the same colour is $k$ independent. Note that any ( $\mathrm{m}, \mathrm{k}$ )-colouring of a graph $G$ partitions the vertex set of $G$ into $m$ subsets $V_{1}, V_{2}, \ldots, V_{m}$ such that every $V_{i}$ is $k$-independent. These sets $\mathrm{V}_{\mathrm{i}}$ are sometimes referred to as the colour classes. The k-defective chromatic number $\chi_{k}(G)$ of $G$ is the smallest positive integer $m$ for which $G$ is $(m, k)$ colourable. Note that $\chi_{0}(\mathrm{G})$ is the usual chromatic number. Clearly $\chi_{\mathrm{k}}(\mathrm{G}) \leq$ $\left\lceil\frac{p}{k+1}\right\rceil$, where $p$ is the order of $G$.

These concepts have been studied by several authors. Hopkins and Staton [11] refer to a k-independent set as a k-small set. Maddox $[15,16]$ and Andrews and Jacobson [3] refer to the same as a k -dependent set. The k -defective chromatic number has been investigated by Frick [7]; Frick and Henning [8]; Maddox [15, 16]; Hopkins and Staton [11] under the name k-partition number; Andrews and Jacobson [3] under the name k-chromatic number.

The Nordhaus-Gaddum (N-G) problem [18] associated with the parameter $\chi_{\mathrm{k}}$ is to find sharp bounds for $\chi_{k}(G)+\chi_{k}(\bar{G})$ and $\chi_{k}(G) \cdot \chi_{k}(\bar{G})$ as $G$ ranges over the class of all graphs of order $p$. Maddox $[15,16]$ investigated the N-G problem for $\chi_{k}$ and proved that if either $G$ or $\bar{G}$ is triangle-free, then $\chi_{k}(G)+\chi_{k}(\bar{G}) \leq 5\left\lceil\frac{p}{3 k+4}\right\rceil$ where $p$ is the order of G . When $\mathrm{k}=1$ he improved the above bound to $6\left\lceil\frac{\mathrm{p}}{9}\right\rceil$. Achuthan et al. [2] proved that $\chi_{1}(G)+\chi_{1}(\bar{G}) \leq \frac{2 p+4}{3}$ for any graph $G$ of order $p$. The $k$-defective chromatic number of a graph is related to the point partition number $\rho_{k}(G)$ defined by Lick and White [13]. It is well known that $\chi_{k}(G) \geq \rho_{k}(G)$. Lick and White [13] established that

$$
\rho_{k}(\mathrm{G})+\rho_{\mathrm{k}}(\overline{\mathrm{G}}) \leq \frac{\mathrm{p}-1}{\mathrm{k}+1}+2
$$

for a graph G of order $p$. Maddox [15] suggested the following conjecture for $k \geq 1$ :
For a graph G of order $p$,

$$
\chi_{k}(\mathrm{G})+\chi_{\mathrm{k}}(\overline{\mathrm{G}}) \leq\left\lceil\frac{\mathrm{p}-1}{\mathrm{k}+1}\right\rceil+2
$$

In [1] we disproved Maddox's conjecture for all $k \geq 1$ by constructing a graph $G$ of order $p \equiv 1(\bmod (k+1))$ with $\chi_{k}(G)+\chi_{k}(\bar{G})=\left\lceil\frac{p-1}{k+1}\right\rceil+3$. These graphs have $P_{4}$ as an induced subgraph and hence Maddox's conjecture can be restated when $G$ ranges over the subclass of $\mathrm{P}_{4}$-free graphs of order p . This restated conjecture is proved for the subclass of $\mathrm{P}_{4}$-free graphs in $[1,19]$ for $k=1,2$. Further, Achuthan et al. [1] established the following weak upper bound:

For a graph G of order $p$,

$$
\chi_{\mathrm{k}}(\mathrm{G})+\chi_{\mathrm{k}}(\overline{\mathrm{G}}) \leq \frac{2 \mathrm{p}+2 \mathrm{k}+4}{\mathrm{k}+2}
$$

Furthermore, they established the following sharp lower bound for the product :
For any graph G of order p,

$$
\chi_{\mathrm{k}}(\mathrm{G}) \cdot \chi_{\mathrm{k}}(\overline{\mathrm{G}}) \geq\left\lceil\frac{\mathrm{p}}{\mathrm{R}-1}\right\rceil
$$

where $R=R(K(1, k+1), K(1, k+1))$. In the same paper they settled the associated realizability problem when $k=1$ and $G$ ranges over the subclass of $P_{4}$-free graphs.

In this paper we will solve the $\mathrm{N}-\mathrm{G}$ problem for the 1 -defective chromatic number over the class of triangle-free graphs. In Section 2 we state some results concerning the 1 -defective chromatic number that will be used repeatedly. In Section 3, we prove that if $G$ or $\bar{G}$ is a triangle-free graph of order $p$ $\geq 3$ then $\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil+2$ and that this bound is sharp. This proves Maddox's conjecture for $\mathrm{k}=1$ over the subclass of triangle-free graphs of order p . Furthermore, we establish a sharp lower bound for $\chi_{k}(G) . \chi_{k}(\overline{\mathrm{G}})$ as $G$ ranges over the class of triangle-free graphs of order $p$.

To prove our results we need to investigate the problem of determining the smallest order of a triangle-free graph with respect to the parameter $\chi_{\mathrm{k}}(\mathrm{G})$. Let $\mathrm{f}(\mathrm{m}, \mathrm{k})$ be the smallest order of a triangle-free graph $G$ such that $\chi_{k}(G)=m$. The determination of $\mathrm{f}(\mathrm{m}, 0)$ is still an open problem (see Toft [21], Problem 29). However partial results concerning this problem have been obtained by several authors (see Mycielski [17], Chvátal [6], Avis [4], Hanson and MacGillivray [10], Grinstead, Katinsky and Van Stone [9], Jensen and Royle [12]).

For notational convenience the path $u_{1}, u_{2}, \ldots, u_{n}$ and the cycle $u_{1}, u_{2}, \ldots, u_{n}, u_{1}$ will be denoted by $u_{1} u_{2} \ldots u_{n}$ and $u_{1} u_{2} \ldots u_{n} u_{1}$ respectively. In all the figures a dotted line between a vertex $u$ and a set A means that all the edges between $u$ and $A$ belong to the complement.

## 2. Some results concerning the 1 -defective chromatic number

The following theorem has been obtained independently by Lovász[14] and Hopkins and Staton [11].

Theorem 1: Let G be a graph with maximum degree $\Delta$. Then

$$
\chi_{k}(G) \leq\left\lceil\frac{\Delta+1}{k+1}\right\rceil \text {. }
$$

The following theorems have been established by Simanihuruk et al. [20].

Theorem 2: The smallest order of a triangle-free graph $G$ such that $\chi_{1}(G)=3$ is 9 , that is, $\mathrm{f}(3,1)=9$.

Theorem 3: Let $G$ be a triangle-free graph of order 9 . Then $\chi_{1}(G)=3$ if and only if $G$ is one of the graphs shown in Figure 1.

Figure 1
Theorem 4: For $m \geq 4$, the smallest order of a triangle-free graph $G$ with $\chi_{1}(G)=m$ is at least $\mathrm{m}^{2}+1$, that is, $\mathrm{f}(\mathrm{m}, 1) \geq \mathrm{m}^{2}+1$.

## 3. Defective colourings of triangle-free graphs and the $\mathbf{N}-\mathbf{G}$ problem:

In this section we establish Maddox's [15] conjecture that

$$
\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil+2
$$

when G ranges over the class of triangle-free graphs of order p . The proof is very technical and makes use of the consequences of the properties $\mathrm{tP}_{3}$ and $D(1, t-1)$ in a triangle-free graph. These consequences are established in a series of lemmas. The assumptions made in the Lemmas 2 to 4 are closely related. We prove Maddox's
conjecture for triangle-free graphs in Theorem 5. Furthermore, we establish a sharp lower bound for the product of $\chi_{k}(G)$ and $\chi_{k}(\bar{G})$ when $G$ ranges over the class of triangle-free graphs.

Lemma 1: Let $G$ be a triangle-free graph of order $p \geq 7$. If $\alpha_{1}(G) \geq p-3$ then $\chi_{1}(G) \leq 2$.

Proof : Firstly if $\alpha_{1}(G) \geq p-2$ then clearly $\chi_{1}(G) \leq 2$. Now assume that $\alpha_{1}(G)=p-3$. Let $U$ be a 1 -independent set of cardinality $p-3$. If $G-U$ has no $P_{3}$ then $\chi_{1}(G) \leq$ 2. Therefore we assume that $G-U$ contains a $P_{3}$. Since $G$ is triangle-free it follows that $G-U$ is isomorphic to $P_{3}$. Let xyz be the $P_{3}$ in $G-U$. We define sets $A, B$, and $C$ as follows: $A=N_{U}(x) \cup N_{U}(z), B=N_{U}(y)$ and $C=U-(A \cup B)$. Now assign colour 1 to the elements of $\{x, z\} \cup B \cup C$ and colour 2 to those of $\{y\} \cup A$. Therefore $\chi_{1}(G) \leq 2$. Hence the lemma.

Lemma 2: Let $G$ be a triangle-free graph of order $p$ with property $t P_{3}$ and without property $D(1, t-1)$. Let $Q_{1}, Q_{2}, \ldots, Q_{t}$ be a collection of vertex disjoint paths of order 3 each. Let $V\left(Q_{i}\right)=\left\{u_{i}, v_{i}, w_{i}\right\}$ where $v_{i}$ is the middle vertex of $Q_{i}$, $1 \leq \mathrm{i} \leq \mathrm{t} ; \mathrm{M}=\bigcup_{\mathrm{i}=1}^{\mathrm{t}} \mathrm{V}\left(\mathrm{Q}_{\mathrm{i}}\right)$ and $\mathrm{F}=\mathrm{V}(\mathrm{G})-\mathrm{M}$. The following hold :
(i) If an end vertex of $Q_{i}$ is adjacent to a vertex of degree one in $G[F]$ then $v_{i}$ has no neighbours in $F$.
(ii) The vertices $u_{i}$ and $w_{i}$ do not have a common neighbour in $F$.

Proof: Since $G$ has property $\mathrm{tP}_{3}$, it follows that F is 1 -independent. Now (i) and (ii) follow from the assumptions that $G$ is triangle-free, $G$ has property $t P_{3}$ and does not have property $D(1, t-1)$.

Lemma 3: Let Gbe a triangle-free graph of order p satisfying the hypothesis of Lemma 2. In addition, the paths $\mathrm{Q}_{1}, \mathrm{Q}_{2}, \ldots, \mathrm{Q}_{\mathrm{t}}$ are chosen such that the number of edges in $\mathrm{G}[\mathrm{F}]$ is as large as possible. Let $A=\{x: x \in F$ and the degree of $x$ in $G[F]$ is 1$\}$ and $B=F-A$. The following hold :
(i) The end vertices $u_{i}$ and $w_{i}$ of $Q_{i}$ have at most one neighbour each in $B$, for all $i, 1 \leq i \leq t ;$
(ii) If $\alpha_{1}(G) \leq p-3 t+1$, then $t \leq 1$.

Proof: Firstly note that F is 1 -independent and thus B is 0 -independent. We will present the proof of $(i)$ for $i=1$. The proof is identical for $i \geq 2$.

Recall that the paths $Q_{1}, Q_{2}, \ldots, Q_{t}$ have been chosen such that the number of edges in $G-M=G[F]$ is as large as possible. Assume that $u_{1}$ has at least two neighbours, say $x$ and $y$ in $B$. Clearly $v_{1}$ and $w_{1}$ are not adjacent to any element of $F$, for otherwise $G$ would have $t+1$ vertex disjoint $P_{3}$ 's, a contradiction to the assumption that $G$ has property $t P_{3}$. Now $x u_{1} y, Q_{2}, \ldots, Q_{t}$ form a set of $t$ vertex disjoint paths of order 3. Thus for $F^{\prime}=(F-\{x, y\}) \cup\left\{v_{1}, w_{1}\right\}$, note that $\left|\mathrm{E}\left(\mathrm{G}\left[\mathrm{F}^{\prime}\right]\right)\right|>|\mathrm{E}(\mathrm{G}[\mathrm{F}])|$, a contradiction to the choice of the $t$ paths $\mathrm{Q}_{1}, \mathrm{Q}_{2}, \ldots, \mathrm{Q}_{\mathrm{t}}$. Thus $u_{1}$ has at most one neighbour in $B$. Similarly it can be shown that $w_{1}$ has at most one neighbour in B. This proves (i).

To prove (ii), let $\alpha_{1}(G) \leq p-3 t+1$. Now suppose that $u_{1}$ and $w_{1}$ are not adjacent to any vertex of $A$. Then it follows from (ii) of Lemma 2 and part (i) above, that $F \cup\left\{u_{1}, w_{1}\right\}$ is a 1-independent set of cardinality $p-3 t+2$, a contradiction. Thus $u_{1}$ or $w_{1}$ is adjacent to a vertex of $A$ and hence, by (i) of Lemma $2, v_{1}$ is not adjacent to any vertex of $F$. If $t \geq 2$, a similar argument will prove that $v_{2}$ is not adjacent to any vertex of $F$. But then $F \cup\left\{v_{1}, v_{2}\right\}$ is a 1 -independent set of cardinality $p-3 t+2$. This contradiction proves (ii).

Lemma 4: Let $G$ be a triangle-free graph of order $p$ satisfying the hypothesis of Lemma 3. Furthermore, suppose that every subgraph of order at most 9 , of $G$ is $(2,1)$ colourable. Also let $t=2$ or 4 and $\chi_{1}(G)=3$ or 4 according as $t=2$ or 4 . Then
(i) $\quad \alpha_{1}(G)=p-3 t+2$,
(ii) for $1 \leq i \leq t$, either $u_{i}$ or $w_{i}$ has no neighbours in $B$,
(iii) there is an $i, 1 \leq i \leq t$, such that the end vertices $u_{i}$ and $w_{i}$ of $Q_{i}$ have no neighbours in $A$ and, for every $j \neq i$, every vertex of $Q_{j}$ is adjacent to atmost one vertex of $\mathrm{Q}_{\mathrm{i}}$,
(iv) for every i, $1 \leq \mathrm{i} \leq \mathrm{t}$, the vertices $\mathrm{u}_{\mathrm{i}}$ and $\mathrm{w}_{\mathrm{i}}$ have no neighbours in A .

Proof: It follows from (ii) of Lemma 3 that $\alpha_{1}(G) \geq p-3 t+2$.
If possible let $\alpha_{1}(G) \geq p-3 t+3$ and $S$ be a 1-independent set of $G$ with $|\mathrm{S}|=\alpha_{1}(\mathrm{G})$. If $\mathrm{t}=2$ then $\alpha_{1}(\mathrm{G}) \geq \mathrm{p}-3$. By Lemma 1 it follows that $\chi_{1}(\mathrm{G}) \leq 2$, a contradiction to our assumption. On the other hand, if $t=4$ then $G-S$ is a graph of order at most 9. By our assumption $\chi_{1}(\mathrm{G}-\mathrm{S}) \leq 2$. Thus $\chi_{1}(\mathrm{G}) \leq \chi_{1}(\mathrm{G}-\mathrm{S})+\chi_{1}(\mathrm{G}[\mathrm{S}]) \leq$ 3. Again this is a contradiction to our assumption that $\chi_{1}(G)=4$ if $t=4$. Thus it follows that $\alpha_{1}(G)=p-3 t+2$ and proves (i).

To prove (ii) we suppose that for some $\mathrm{i}, 1 \leq \mathrm{i} \leq \mathrm{t}$, both the vertices $\mathrm{u}_{\mathrm{i}}$ and $\mathrm{w}_{\mathrm{i}}$ have a neighbour in B. Let $x$ be the neighbour of $u_{i}$ and $y$ be the neighbour of $w_{i}$. Clearly $\mathrm{x} \neq \mathrm{y}$. Now we can easily construct paths $\mathrm{Q}_{1}^{\prime}, \mathrm{Q}_{2}^{\prime}, \ldots, \mathrm{Q}_{\mathrm{t}}^{\prime}$ such that $\left|\mathrm{E}\left(\mathrm{G}-\bigcup_{\mathrm{i}=1}^{\mathrm{t}} \mathrm{V}\left(\mathrm{Q}_{\mathrm{i}}^{\prime}\right)\right)\right|>|\mathrm{E}(\mathrm{G}[\mathrm{F}])|$ a contradiction to the choice of $\mathrm{Q}_{1}, \mathrm{Q}_{2}, \ldots, \mathrm{Q}_{\mathrm{t}}$. This proves (ii).

To prove the first part of (iii) assume that for each $\mathrm{i}, 1 \leq \mathrm{i} \leq \mathrm{t}$, an end vertex of $Q_{i}$ has a neighbour in $A$. Without any loss of generality assume that $u_{i}$ has a neighbour, say $a_{i}$, in $A$, for each $i, 1 \leq i \leq t$. Note that $a_{i}$ may be equal to $a_{j}$ for some $i \neq j$. Let $b_{i}$ be the neighbour of $a_{i}$ in A. If for some $i, w_{i}$ has a neighbour in $F-\left\{b_{i}\right\}$ then $G$ would have $t+1$ vertex disjoint $P_{3}$ 's, a contradiction to the maximality of $t$. Thus it follows that $w_{i}$ has no neighbours in $F-\left\{b_{i}\right\}$, for $1 \leq i \leq t$.

Now we prove the following claim.

Claim : For each $\mathrm{i}, \mathrm{l} \leq \mathrm{i} \leq \mathrm{t}, \mathrm{w}_{\mathrm{i}}$ is adjacent to $\mathrm{b}_{\mathrm{i}}$
Suppose not. Without any loss of generality we assume that $w_{1}$ is not adjacent to $b_{1}$. Now from (i) of Lemma 2 it follows that $\mathrm{F} \cup\left\{\mathrm{v}_{1}, \mathrm{w}_{1}\right\}$ is 1 -independent. From part (i) of this lemma, it follows that $\mathrm{F} \cup\left\{\mathrm{v}_{1}, \mathrm{w}_{1}\right\}$ is a maximal 1-independent set. Let $\mathrm{I}=\mathrm{F} \cup\left\{\mathrm{v}_{1}, \mathrm{w}_{1}\right\}$ (see Figure 2.a). Consider the centre vertex $\mathrm{v}_{2}$ of $\mathrm{Q}_{2}$. Since $\mathrm{v}_{2}$ is not adjacent to any vertex of $F$ and $I$ is maximal 1 -independent it follows that $\mathrm{v}_{2}$ is adjacent to one of $v_{1}$ and $w_{1}$. Since $G$ is triangle- free it follows that $v_{2}$ is adjacent to exactly one of $\mathrm{v}_{1}$ and $\mathrm{w}_{1}$.

Figure 2

Firstly let $v_{2}$ be adjacent to $w_{1}$ (see Figure 2.b). Since G is triangle-free and does not possess the property $D(1, t-1)$ it follows that the vertex $u_{2}$ is not adjacent to either of $w_{1}$ and $v_{1}$. For the same reason we can conclude that $w_{2}$ is not adjacent to either of $v_{1}$ and $w_{1}$. Recall that $a_{2}$ is the neighbour of $u_{2}$ in $A$. Now if $w_{2}$ is not adjacent to $b_{2}$ then $I \cup\left\{w_{2}\right\}$ would form a 1 -independent set contradicting the maximality of $I$. Therefore $w_{2}$ is adjacent to $b_{2}$. Note that the edge $\left(a_{2}, b_{2}\right)$ may be the same as the edge $\left(a_{1}, b_{1}\right)$ (see Figure 2.c). Now consider the set $I^{\prime}=I \cup\left\{u_{2}, w_{2}\right\}-\left\{a_{2}\right\}$ of size $p-3 t+3$. It is easy to see that $I^{\prime}$ is 1 -independent contradicting the fact that $\alpha_{1}(G)=p-3 t+2$. Hence the claim is proved in case $\mathrm{v}_{2}$ is adjacent to $\mathrm{w}_{1}$. A similar contradiction can be arrived at, if we assume that $v_{2}$ is adjacent to $v_{1}$. This proves the claim.

To complete the proof of the first part of (iii) we will consider the cases $t=4$ and $t=2$ separately and arrive at a contradiction in each case.

Firstly let $t=4$. Consider the set $F \cup\left\{\mathrm{v}_{1}, \mathrm{v}_{2}, \mathrm{v}_{3}, \mathrm{v}_{4}\right\}$. Recall that $\mathrm{v}_{\mathrm{i}}$ is the central vertex of the path $Q_{i}$ and that $v_{i}$ has no neighbours in $F$, for $1 \leq i \leq 4$. Now $|F|=p-12$ and $\alpha_{1}(G)=p-10$. Hence for every subset $S$ of size 3 of $\left\{v_{1}, v_{2}, v_{3}, v_{4}\right\}$, $G[S]$ contains a $P_{3}$. It can easily be seen that $G\left[\left\{v_{1}, v_{2}, v_{3}, v_{4}\right\}\right]$ is isomorphic to a cycle, say $C=v_{1} v_{2} v_{3} V_{4} v_{1}$. Now if the edge $\left(a_{1}, b_{1}\right) \neq$ the edge $\left(a_{2}, b_{2}\right)$ then $G$ has 5 vertex disjoint $P_{3}$ 's namely $u_{1} a_{1} b_{1}, W_{1} v_{1} v_{2}, u_{2} a_{2} b_{2}, Q_{3}, Q_{4}$, contradicting the property $t P_{3}$ i.e. $4 P_{3}$. Thus $\left(a_{1}, b_{1}\right)=\left(a_{2}, b_{2}\right)$. Similarly it can be shown that $\left(a_{2}, b_{2}\right)=\left(a_{3}, b_{3}\right)=\left(a_{4}, b_{4}\right)$. Let $\mathrm{W}=\bigcup_{\mathrm{i}=1}^{4} \mathrm{~V}\left(\mathrm{Q}_{\mathrm{i}}\right) \cup\left\{\mathrm{a}_{1}, \mathrm{~b}_{1}\right\}$. Note that $|\mathrm{W}|=14$. From Theorem 4, it follows that $\chi_{1}(G[W]) \leq 3$. It is easy to show that there are no edges between $W$ and $F-\left\{a_{1}, b_{1}\right\}$. Thus $\chi_{1}(G)=\chi_{1}(G[W])$ and hence $\chi_{1}(G) \leq 3$, a contradiction to our assumption that $\chi_{1}(G)=4$.

Next let $t=2$. We will first assume that $\left(a_{1}, b_{1}\right) \neq\left(a_{2}, b_{2}\right)$ (see Figure 3.a).

## Figure 3

Consider the cycle $C=u_{1} V_{1} w_{1} b_{1} a_{1} u_{1}$. If there is an edge between $V(C)$ and $V(G)-V(C)$, then there are three vertex disjoint $P_{3}$ 's, a contradiction to the property $t_{3}$ with $t=2$. Thus there are no edges between $V(C)$ and $V(G)-V(C)$. Similarly there are no edges between the vertices of the cycle $u_{2} \mathrm{~V}_{2} \mathrm{w}_{2} \mathrm{~b}_{2} \mathrm{a}_{2} \mathrm{u}_{2}$ and the rest of the vertices in $G$. Thus it follows that every connected component of $G$ is either a $C_{5}$ or a $K_{2}$ or a $\mathrm{K}_{1}$. Thus $\chi_{1}(\mathrm{G})=2$, a contradiction to our assumption that $\chi_{1}(\mathrm{G})=3$.

Now assume that $\left(\mathrm{a}_{1}, \mathrm{~b}_{1}\right)=\left(\mathrm{a}_{2}, \mathrm{~b}_{2}\right)$ (see Figure $3 . \mathrm{b}$ ). Since G is triangle-free, $\left(w_{1}, w_{2}\right),\left(u_{1}, u_{2}\right),\left(u_{1}, w_{1}\right)$, and $\left(u_{2}, w_{2}\right)$ are not edges of $G$. Clearly there are no edges between $\left\{u_{1}, w_{1}, u_{2}, w_{2}\right\}$ and $F-\left\{a_{1}, b_{1}\right\}$. Thus $\left\{u_{1}, w_{1}, u_{2}, w_{2}\right\} \cup F-\left\{a_{1}, b_{1}\right\}$ is a $1-$ independent set. Now we assign colour 1 to $\left\{\mathrm{u}_{1}, \mathrm{w}_{1}, \mathrm{u}_{2}, \mathrm{w}_{2}\right\} \cup \mathrm{F}-\left\{\mathrm{a}_{1}, \mathrm{~b}_{1}\right\}$ and colour 2 to $\left\{\mathrm{v}_{1}, \mathrm{v}_{2}, \mathrm{a}_{1}, \mathrm{~b}_{1}\right\}$. Thus $\chi_{1}(\mathrm{G}) \leq 2$, a contradiction. This completes the proof of the first part of (iii).

To prove the second part of (iii), we assume without any loss of generality that $u_{1}$ and $w_{1}$ of $Q_{1}$ have no neighbours in $A$. Now using part (ii) of Lemma 2 it follows that $F \cup\left\{u_{1}, w_{1}\right\}$ is 1 -independent. Define $J=F \cup\left\{u_{1}, w_{1}\right\}$. Since $\alpha_{1}(G)=p-3 t+2$ it follows that J is a maximal 1 -independent set. Note that by (ii), either $u_{1}$ or $w_{1}$ has no neighbours in $B$. Without loss of generality we assume that $w_{1}$ has no neighbours in $B$.

Also note that by (i) of Lemma 3, $u_{1}$ has at most one neighbour in $B$. We now consider the two cases separately to establish the second part of (iii).

Case 1: $u_{1}$ has no neighbours in $B$.
Note that $B \cup\left\{u_{1}, w_{1}\right\}$ is 0 -independent. Since $J=F \cup\left\{u_{1}, w_{1}\right\}$ is a maximal 1independent set, it follows that for any vertex $z$ of $Q_{i}$, for $i \geq 2$, either $z$ has a neighbour in A or has two neighbours in $B \cup\left\{u_{1}, w_{1}\right\}$. Suppose $z$ is a vertex of $Q_{i}, i \geq 2$, such that $z$ is adjacent to $u_{1}$ and $w_{1}$ (see Figure 4).

Figure 4

Let $z^{\prime}$ be a neighbour of $z$ in $Q_{i}$. Since $G$ is triangle-free, $z^{\prime}$ is not adjacent to $u_{1}$ or $w_{1}$. From the maximality of $J$, either $z^{\prime}$ is adjacent to a vertex of $A$ or is adjacent to at least two vertices of $B$. In either case $G$ has the property $D(1, t-1)$, a contradiction to our assumption. This proves (iii) in Case 1.

Case 2: $u_{1}$ has a neighbour, say $x$, in $B$.
Note that $\left\{w_{1}\right\} \cup B-\{x\}$ is 0 -independent. Again since $J=F \cup\left\{u_{1}, w_{1}\right\}$ is a maximal 1-independent set, it follows that for any vertex $z$ of $Q_{i}, i \geq 2$, either $z$ has a neighbour in $A \cup\left\{u_{1}, x\right\}$ or it has two neighbours in $\left\{w_{1}\right\} \cup B-\{x\}$.

Suppose z is a vertex of $\mathrm{Q}_{\mathrm{i}}, \mathrm{i} \geq 2$, such that z is adjacent to $\mathrm{u}_{1}$ and $\mathrm{w}_{1}$ (see Figure 5). Let $z^{\prime}$ be a neighbour of $z$ in $Q_{i}$.

Figure 5
Firstly note that $z^{\prime}$ is not adjacent to $u_{1}$ or $w_{1}$. From the maximality of $J$ we have one of the following :
(a) $\mathrm{z}^{\prime}$ is adjacent to a vertex of A ;
(b) $\mathrm{z}^{\prime}$ is adjacent to at least two vertices of $\mathrm{B}-\{\mathrm{x}\}$;
(c) $z^{\prime}$ is adjacent to $x$.

If (a) or (b) is true then $G$ has the property $D(1, t-1)$, a contradiction to our assumption. Thus $\mathrm{z}^{\prime}$ is adjacent to x .

Now suppose that $z$ is an end vertex of $Q_{i}$, say $z=u_{i}$. Then $z^{\prime}=v_{i}$. The cycle $u_{i} W_{1} v_{1} u_{1} u_{i}$, the paths $x v_{i} W_{i}$ and $Q_{\alpha}, \alpha \neq 1$ and $i$ imply that $G$ has the property $D(1, t-1)$, a contradiction to our assumption. Thus it follows that $z$ is the centre vertex $v_{i}$ of $Q_{i}$ (see Figure 6).

Figure 6

Now consider the vertex $u_{i}$. By part (ii), $u_{i}$ has no neighbours in B. Since G is triangle-free $u_{i}$ is not adjacent to either $u_{1}$ or $w_{1}$. The maximality of $J$ implies that $u_{i}$ is adjacent to a vertex of A . Again it can be shown that G has the property $\mathrm{D}(1, \mathrm{t}-1)$, a contradiction. This completes the proof of (iii) in Case 2.

We now present the proof of (iv). Since $J$ is 1 -independent, clearly (iv) is true for $\mathrm{i}=1$. We will prove (iv) for $\mathrm{i}=2$. The proof for $\mathrm{i} \geq 3$ is identical.

Suppose $u_{2}$ is adjacent to a vertex $a_{1}$ in $A$. Let $b_{1}$ be the neighbour of $a_{1}$ in $A$ (see Figure 7.a). From (i) of Lemma 2, it follows that $\mathrm{v}_{2}$ is not adjacent to any vertex of $A \cup B$. Since $J=\left\{u_{1}, w_{1}\right\} \cup F$ is maximal 1 -independent, the vertex $v_{2}$ has to be adjacent to at least one of the vertices $u_{1}$ and $w_{1}$. Combining this with (iii) of this lemma, we conclude that the vertex $\mathrm{v}_{2}$ is adjacent to exactly one vertex of $\left\{\mathrm{u}_{1}, \mathrm{w}_{1}\right\}$. Without any loss of generality assume that $v_{2}$ is adjacent to $u_{1}$ (see Figure 7.b). Now consider the set $J \cup\left\{v_{2}\right\}$. It has $p-3 t+3$ vertices. Since $\alpha_{1}(G)=p-3 t+2$ and $v_{2}$ is not adjacent to any vertex of $F$ (by Lemma 2) it follows that $u_{1}$ is adjacent to a vertex, say d, of B (see Figure 7.c).

(a)

(c)

(b)

(d)

Figure 7

Now if $\left(w_{2}, w_{1}\right) \in E(G)$ then $G$ has $(t+1) P_{3}$ 's namely $w_{2} w_{1} v_{1}, v_{2} u_{1} d, u_{2} a_{1} b_{1}$ and the $t-2$ paths $Q_{3}, \ldots, Q_{t}$. This is a contradiction to the assumption that $G$ has the property $\mathrm{tP}_{3}$. Thus $w_{2}$ is not adjacent to $w_{1}$. Also since $G$ is triangle-free, $w_{2}$ is not adjacent to $u_{1}$. Using (ii) of Lemma 2 and the fact that $t$ is the largest number of vertex disjoint 3paths in G, we conclude that $w_{2}$ has no neighbours in $F-\left\{b_{1}\right\}$. Now if $w_{2}$ is not adjacent to $b_{1}$, then $J \cup\left\{w_{2}\right\}$ forms a 1 -independent set contradicting part (i). Thus it follows that $\left(w_{2}, b_{1}\right) \in E(G)$ (see Figure 7.d). Consider the vertex $u_{2}$ in Figure 7.d. Clearly $u_{2}$ is not adjacent to $w_{1}$, otherwise $G$ has $(t+1) P_{3}$ 's. Now $\mathrm{J} \cup\left\{\mathrm{u}_{2}, \mathrm{w}_{2}\right\}-\left\{\mathrm{a}_{1}\right\}$ is a 1 -independent set of cardinality $\mathrm{p}-3 \mathrm{t}+3$, a contradiction to the fact that $\alpha_{1}(\mathrm{G})=\mathrm{p}-3 \mathrm{t}+2$. This proves that $u_{2}$ does not have any neighbours in A. Similarly it can be shown that $\mathrm{w}_{2}$ has no neighbours in A .

This completes the proof of (iv) and hence Lemma 4.

Theorem 5 : Let G be a triangle-free graph of order p . Then

$$
\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil+2 .
$$

Moreover this bound is sharp for $p \geq 3$.
Proof : Firstly let $\chi_{1}(\mathrm{G}) \leq 2$. If $\chi_{1}(\mathrm{G})=1$ then $\chi_{1}(\overline{\mathrm{G}})=\left\lceil\frac{\mathrm{p}}{2}\right\rceil$. Hence $\chi_{1}(\mathrm{G})$ $+\chi_{1}(\overline{\mathrm{G}}) \leq\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil+2$. If $\chi_{1}(\mathrm{G})=2$ then $G$ has a path P of order 3. The vertices of the path $P$ form a 1 -independent set in $\bar{G}$ and consequently $\chi_{1}(\bar{G})$ $\leq\left\lceil\frac{p-3}{2}\right\rceil+1=\left\lceil\frac{p-1}{2}\right\rceil$. Hence the required inequality.

Henceforth we assume that $\chi_{1}(\mathrm{G}) \geq 3$. From Theorems 2 and 4 , it follows that $\mathrm{p} \geq 9$. We prove Theorem 5 by induction on p . Let G be a triangle-free graph of order 9. From Theorem 4 we have $\chi_{1}(G) \leq 3$. Thus $\chi_{1}(G)=3$. Now by Theorem 3, G is isomorphic to one of the graphs $\mathrm{G}_{\mathrm{i}}, 1 \leq \mathrm{i} \leq 4$, in Figure 1. It is easy to see that
$\mathrm{u}_{1} \mathrm{w}_{3} \mathrm{u}_{2} \mathrm{w}_{1} \mathrm{u}_{1}$ and $\mathrm{u}_{3} \mathrm{w}_{4} \mathrm{u}_{4} \mathrm{w}_{2} \mathrm{u}_{3}$ form vertex disjoint $\mathrm{C}_{4}$ 's in $\mathrm{G}_{\mathrm{i}}$, for $1 \leq \mathrm{i} \leq 3$. Similarly the two 4 -cycles $u_{1} w_{3} u_{2} w_{1} u_{1}$ and $u_{3} w_{2} u_{4} z u_{3}$ are vertex disjoint in $G_{4}$. Now the vertex sets of these $C_{4}$ 's are 1 -independent in the graph $\bar{G}$. Thus $\chi_{1}(\overline{\mathrm{G}}) \leq 3$. Hence $\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq 6$. This establishes the basis for induction.

Now let $\mathrm{p} \geq 10$. We make the induction hypothesis that the theorem is true for any triangle-free graph of order less than p and then prove it for any triangle-free graph of order $p$.

Case 1: There is a subset $L$ of cardinality 9 of $V(G)$ such that $\chi_{1}(G[L]) \geq 3$.
From Theorem 4 we have $\chi_{1}(G[L]) \leq 3$. Thus $\chi_{1}(G[L])=3$. By Theorem 3, G[L] is isomorphic to one of the graphs shown in Figure 1. As mentioned before, each of these graphs has two vertex disjoint $\mathrm{C}_{4}$ 's. Recall that the vertex set of a $C_{4}$ in $G$ is a 1 -independent set in $\bar{G}$. Now if $X$ is the vertex set of the union of the two $\mathrm{C}_{4}$ 's in $\mathrm{G}[\mathrm{L}]$ then $\chi_{1}(\overline{\mathrm{G}}[\mathrm{X}]) \leq 2$. From Theorem 2 we have $\chi_{1}(\mathrm{G}[\mathrm{X}]) \leq 2$ since $|\mathrm{V}(\mathrm{G}[\mathrm{X}])|=8$. Now using these inequalities and the induction hypothesis we have

$$
\begin{aligned}
\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) & \leq \chi_{1}(\mathrm{G}-\mathrm{X})+\chi_{1}(\overline{\mathrm{G}}-\mathrm{X})+\chi_{1}(\mathrm{G}[\mathrm{X}])+\chi_{1}(\overline{\mathrm{G}}[\mathrm{X}]) \\
& \leq\left\lceil\frac{\mathrm{p}-9}{2}\right\rceil+2+2+2=\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil+2
\end{aligned}
$$

This proves the theorem in this case.
Case 2 : For every subset $L$ of cardinality 9 of $V(G), \chi_{1}(G[L]) \leq 2$
Since $\chi_{1}(G) \geq 3, G$ contains a $P_{3}$. Let $t$ be the largest number of vertex disjoint paths of order 3 in $G$, i.e. $G$ has the property $t P_{3}$. Let $Q_{1}, Q_{2}, \ldots, Q_{t}$ be $t$ vertex disjoint paths of order 3 in $G$. Let $M=\bigcup_{i=1}^{t} V\left(Q_{i}\right)$ and $V\left(Q_{i}\right)=\left\{u_{i}, v_{i}, w_{i}\right\}$ such that $u_{i}$ and $\mathrm{w}_{\mathrm{i}}$ are the end vertices of $\mathrm{Q}_{\mathrm{i}}$ for $1 \leq \mathrm{i} \leq \mathrm{t}$.

Note that $V(G)-M$ is 1 -independent in $G$. Without any loss of generality we can assume that the paths $Q_{1}, Q_{2}, \ldots, Q_{t}$ have been chosen such that the number of edges in $G-M$ is as large as possible. This means that if $R_{1}, R_{2}, \ldots, R_{t}$ are vertex disjoint
paths of order 3 in $G$ and $Y=\bigcup_{i=1}^{t} V\left(R_{i}\right)$ then $|E(G-M)| \geq|E(G-Y)|$. Note that the subgraph $\overline{\mathrm{G}}\left[\mathrm{V}\left(\mathrm{Q}_{\mathrm{i}}\right)\right]$ is $\mathrm{P}_{3}$-free for each i . Thus

$$
\begin{equation*}
\chi_{1}(\overline{\mathrm{G}}[\mathrm{M}]) \leq \mathrm{t} . \tag{1}
\end{equation*}
$$

Since $\bar{G}-M$ is a graph of order $p-3 t$, we have $\chi_{1}(\bar{G}-M) \leq\left\lceil\frac{p-3 t}{2}\right\rceil$. Combining this with (1) we have

$$
\begin{equation*}
\chi_{1}(\overline{\mathrm{G}}) \leq \chi_{1}(\overline{\mathrm{G}}[\mathrm{M}])+\chi_{1}(\overline{\mathrm{G}}-\mathrm{M}) \leq \mathrm{t}+\left\lceil\frac{\mathrm{p}-3 \mathrm{t}}{2}\right\rceil=\left\lceil\frac{\mathrm{p}-\mathrm{t}}{2}\right\rceil . \tag{2}
\end{equation*}
$$

Also

$$
\begin{equation*}
\chi_{1}(\mathrm{G}) \leq \chi_{1}(\mathrm{G}[\mathrm{M}])+\chi_{1}(\mathrm{G}-\mathrm{M})=\chi_{1}(\mathrm{G}[\mathrm{M}])+1, \tag{3}
\end{equation*}
$$

since $V(G)-M$ is 1 -independent in $G$.
First let $\mathrm{t} \geq 8$ and let $\mathrm{N}=\bigcup_{\mathrm{i}=1}^{8} \mathrm{~V}\left(\mathrm{Q}_{\mathrm{i}}\right)$. Note that $|\mathrm{N}|=24$. By Theorem 4,
$\mathrm{f}(5,1) \geq 26$ and thus we have $\chi_{1}(\mathrm{G}[\mathrm{N}]) \leq 4$. Since $\mathrm{V}\left(\mathrm{Q}_{\mathrm{i}}\right)$ is a 1 -independent set in $\overline{\mathrm{G}}$ for each $\mathrm{i}, 1 \leq \mathrm{i} \leq \mathrm{t}$, it follows that $\chi_{1}(\overline{\mathrm{G}}[\mathrm{N}]) \leq 8$. Now $\chi_{1}(\mathrm{G}) \leq \chi_{1}(\mathrm{G}[\mathrm{N}])+\chi_{1}(\mathrm{G}-\mathrm{N})$ and $\chi_{1}(\overline{\mathrm{G}}) \leq \chi_{1}(\overline{\mathrm{G}}[\mathrm{N}])+\chi_{1}(\overline{\mathrm{G}}-\mathrm{N})$. Thus

$$
\begin{aligned}
\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) & \leq \chi_{1}(\mathrm{G}[\mathrm{~N}])+\chi_{1}(\overline{\mathrm{G}}[\mathrm{~N}])+\chi_{1}(\mathrm{G}-\mathrm{N})+\chi_{1}(\overline{\mathrm{G}}-\mathrm{N}) \\
& \leq 12+\chi_{1}(\mathrm{G}-\mathrm{N})+\chi_{1}(\overline{\mathrm{G}}-\mathrm{N}) .
\end{aligned}
$$

By the induction hypothesis

$$
\chi_{1}(\mathrm{G}-\mathrm{N})+\chi_{1}(\overline{\mathrm{G}}-\mathrm{N}) \leq\left\lceil\frac{\mathrm{p}-25}{2}\right\rceil+2 .
$$

Therefore,

$$
\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil+2 .
$$

Thus the theorem is proved when $t \geq 8$.
Henceforth let us assume that $t \leq 7$. From (2) and (3) we have

$$
\begin{equation*}
\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq \chi_{1}(\mathrm{G}[\mathrm{M}])+1+\left\lceil\frac{\mathrm{p}-\mathrm{t}}{2}\right\rceil . \tag{4}
\end{equation*}
$$

Note that $\mathrm{t} \geq 2$, for otherwise, $\alpha_{1}(\mathrm{G}) \geq \mathrm{p}-3$ and thus by Lemma 1, we have $\chi_{1}(\mathrm{G}) \leq 2$, contradicting our assumption that $\chi_{1}(G) \geq 3$.

Subcase 2.1 : t is odd, $2 \leq \mathrm{t} \leq 7$.
Firstly let $\mathrm{t}=3$. Since every subgraph of order 9 can be coloured with 2 colours and $|M|=9$, it follows that $\chi_{1}(G[M])=2$. Incorporating this in (4) we have

$$
\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq 2+1+\left\lceil\frac{\mathrm{p}-3}{2}\right\rceil=\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil+2 .
$$

Hence the theorem is proved in this case when $t=3$.
Finally let $t=5$ or 7 . Accordingly G[M] has order 15 or 21. From Theorems 2 and 4 we have $\chi_{1}(G[M]) \leq 3$ or 4 according as $t=5$ or 7 . Incorporating this in (4) we have the required inequality. This proves the theorem in Subcase 2.1.

Subcase 2.2: t is even, $2 \leq \mathrm{t} \leq 6$.
We will first show that if $G$ has the property $D(1, t-1)$ then $\chi_{1}(G)$ $+\chi_{1}(\overline{\mathrm{G}}) \leq 2+\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil$. Assume that G has the property $\mathrm{D}(1, \mathrm{t}-1)$. Let $\mathrm{R}_{1}, \mathrm{R}_{2}$,
$\ldots, \mathrm{R}_{\mathrm{t}-1}$ be $\mathrm{t}-1$ vertex disjoint paths of order 3 and C a cycle of order 4 which is vertex disjoint from each $R_{i}$. Let $Z=\left\{\bigcup_{i=1}^{t-1} V\left(R_{i}\right)\right\} \cup V(C)$. Clearly $|Z|=3 t+1$. It is easy to see that $\chi_{1}(\overline{\mathrm{G}}[\mathrm{Z}]) \leq \mathrm{t}$ and $\chi_{1}(\overline{\mathrm{G}}-\mathrm{Z}) \leq\left\lceil\frac{\mathrm{p}-3 \mathrm{t}-1}{2}\right\rceil$. Therefore

$$
\begin{equation*}
\chi_{1}(\overline{\mathrm{G}}) \leq \mathrm{t}+\left\lceil\frac{\mathrm{p}-3 \mathrm{t}-1}{2}\right\rceil=\left\lceil\frac{\mathrm{p}-\mathrm{t}-1}{2}\right\rceil . \tag{5}
\end{equation*}
$$

We will now prove that $\chi_{1}(\mathrm{G}) \leq 3$ or 4 or 5 according as $\mathrm{t}=2$ or 4 or 6 . Note that G[Z] has order 7 or 13 or 19 according as $t=2$ or 4 or 6 . From Theorems 2 and 4 we have $\chi_{1}(\mathrm{G}[\mathrm{Z}]) \leq 2$ or 3 or 4 according as $t=2$ or 4 or 6 . From the maximality of $t$, it follows that $\mathrm{V}(\mathrm{G})-\mathrm{Z}$ is 1 -independent in G and hence $\chi_{1}(\mathrm{G}-\mathrm{Z})=1$. Thus $\chi_{1}(\mathrm{G}) \leq$ $\chi_{1}(\mathrm{G}[\mathrm{Z}])+\chi_{1}(\mathrm{G}-\mathrm{Z}) \leq 3$ or 4 or 5 according as $\mathrm{t}=2$ or 4 or 6 . Now combining this
inequality with (5) we have the required inequality. This proves the theorem when G has the property $D(1, t-1)$.

From now onwards we will assume that $G$ does not possess the property $\mathrm{D}(1, \mathrm{t}-1)$. We will first introduce the following notation. Let $\mathrm{F}=\mathrm{V}(\mathrm{G})-\mathrm{M}$. Clearly F is 1 -independent in $G$. Now Let $A=\{x: x \in F$ and the degree of $x$ in $G[F]$ is 1$\}$ and $\mathrm{B}=\mathrm{F}-\mathrm{A}$. Clearly B is 0 -independent in $G$. Recall that $u_{i}$ and $w_{i}$ are the end vertices and $v_{i}$ is the centre vertex of the path $\mathrm{Q}_{\mathrm{i}}, 1 \leq \mathrm{i} \leq \mathrm{t}$. We divide the rest of the proof into two more subcases based on the value of $t$.

Subcase 2.2.1: $\mathrm{t}=6$.
From (ii) of Lemma 3, it follows that $\alpha_{1}(\mathrm{G}) \geq \mathrm{p}-3 \mathrm{t}+2=\mathrm{p}-16$. Thus there is a 1 -independent set $R$ of size at least $p-16$. Since $f(4,1) \geq 17$, the subgraph G-R is (3,1)-colourable. Hence $\chi_{1}(\mathrm{G}) \leq 4$. Combining this with inequality (2) we have $\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq 4+\left\lceil\frac{\mathrm{p}-6}{2}\right\rceil \leq\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil+2$, which proves the theorem in this subcase.
Subcase 2.2.2: $\mathrm{t}=2$ or 4 .
Recall that $\chi_{1}(G) \geq 3$ and $G$ does not possess the property $D(1, t-1)$. Note that $\mathrm{G}[\mathrm{M}]$ is a graph of order 6 or 12 according as $t=2$ or 4 . Thus from Theorems 2 and 4 it follows that $\chi_{1}(\mathrm{G}[\mathrm{M}]) \leq 2$ or 3 according as $\mathrm{t}=2$ or 4 . Incorporating this in inequality (3) we have $\chi_{1}(\mathrm{G}) \leq 3$ or 4 according as $\mathrm{t}=2$ or 4 . Thus we have

$$
\chi_{1}(\mathrm{G})=\left\{\begin{array}{l}
3, \text { if } \mathrm{t}=2 \\
3 \text { or } 4, \text { if } \mathrm{t}=4
\end{array}\right.
$$

Firstly let $\mathrm{t}=4$ and $\chi_{1}(\mathrm{G})=3$. From (2), $\chi_{1}(\overline{\mathrm{G}}) \leq\left\lceil\frac{\mathrm{p}-4}{2}\right\rceil$. Thus

$$
\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq 3+\left\lceil\frac{\mathrm{p}-4}{2}\right\rceil \leq 2+\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil .
$$

This proves the theorem when $\mathrm{t}=4$ and $\chi_{1}(\mathrm{G})=3$. Henceforth we will assume that

$$
x_{1}(\mathrm{G})=\left\{\begin{array}{l}
3,  \tag{6}\\
\text { if } \mathrm{t}=2 \\
4,
\end{array} \text { if } \mathrm{t}=4 .\right.
$$

We will show that this will lead to a contradiction. By (ii) of Lemma 2 and (iii) of Lemma 4 we may assume that $\mathrm{F} \cup\left\{\mathrm{u}_{1}, \mathrm{w}_{1}\right\}$ is a 1 -independent set and that each vertex of $\mathrm{Q}_{2}$ is adjacent to at most one vertex of $\mathrm{Q}_{1}$. Define $\mathrm{J}=\mathrm{F} \cup\left\{\mathrm{u}_{1}, \mathrm{w}_{1}\right\}$. Note that J is maximal 1 -independent by (i) of Lemma 4.

Now we arrive at the final contradiction. Using Lemma 4 we can assume without any loss of generality that, the vertices $\mathrm{w}_{1}, \mathrm{w}_{2}, \ldots, \mathrm{w}_{\mathrm{t}}$ do not have any neighbours in F (see Figure 8.a).

Figure 8
If $\mathrm{w}_{1}$ is not adjacent to $\mathrm{u}_{2}$ then $\mathrm{F} \cup\left\{\mathrm{w}_{1}, \mathrm{u}_{2}, \mathrm{w}_{2}\right\}$ is a 1 -independent set of cardinality $p-3 t+3$, a contradiction to the fact $\alpha_{1}(G)=p-3 t+2$. Similarly if $u_{1}$ is not
adjacent to $w_{2}$ then $J \cup\left\{w_{2}\right\}$ forms a 1 -independent set of cardinality $p-3 t+3$, a contradiction. Thus $\left(u_{2}, w_{1}\right)$ and $\left(u_{1}, w_{2}\right)$ are edges of $G$. This implies that $\left(u_{2}, u_{1}\right)$ and ( $w_{2}, w_{1}$ ) are not edges of $G$ (see Figure 8.b). Consider the vertex $u_{2}$ of Figure 8.b. By Lemma $4, u_{2}$ is not adjacent to any vertex of $A$. Since $J$ is maximal it follows that $u_{2}$ is adjacent to a vertex, say $\mathrm{c}_{1}$, of B (see Figure 8.c).

Now consider the vertex $v_{2}$ in Figure 8.c. Since $G$ is triangle-free, $v_{2}$ is adjacent to neither $u_{1}$ nor $w_{1}$. Since $J$ is a maximal 1 -independent set, $v_{2}$ is adjacent to at least one vertex of $A \cup B$. Now if $v_{2}$ has a neighbour in $A$, it is easy to show that $G$ has the property $(t+1) \mathrm{P}_{3}$, a contradiction. Hence $\mathrm{v}_{2}$ does not have neighbours in A and thus it has a neighbour in B . If $\mathrm{v}_{2}$ has at least two neighbours in B , again we can show that $G$ has the property $(t+1) \mathrm{P}_{3}$. Thus it follows that $\mathrm{v}_{2}$ has exactly one neighbour, say $c_{2}$, in B. Since $G$ is triangle-free, $c_{2} \neq c_{1}$ (see Figure 8.d)). Clearly $c_{2}$ is adjacent to $u_{1}$, otherwise $J \cup\left\{\mathrm{v}_{2}\right\}$ is a 1 -independent set of cardinality $\mathrm{p}-3 \mathrm{t}+3$, a contradiction to $\alpha_{1}(G)=p-3 t+2$. Now the paths $Q_{1}^{\prime}=v_{1} w_{1} u_{2}, Q_{3}, \ldots, Q_{t}$ and the cycle $C_{4}=c_{2} u_{1} w_{2} v_{2} c_{2}$, imply that $G$ has the property $D(1, t-1)$, a contradiction. This forms the final contradiction for the Subcase 2.2.2.

Thus we have shown that $\chi_{1}(\mathrm{G})+\chi_{1}(\overline{\mathrm{G}}) \leq\left\lceil\frac{\mathrm{p}-1}{2}\right\rceil+2$. The graph $\mathrm{G} \cong \mathrm{K}(1, \mathrm{p}-1)$ shows that the above inequality is sharp for $\mathrm{p} \geq 3$. This completes the proof of Theorem 5.

We now determine the Ramsey number $R^{\prime}(K(1, k+1), K(1, k+1))$, for every positive integer k . Consider a triangle-free graph G of order $\mathrm{R}(\mathrm{K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1))$. By the definition of the generalized Ramsey number $\mathrm{R}(\mathrm{K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1))$, it follows that either G or $\overline{\mathrm{G}}$ contains $\mathrm{K}(1, \mathrm{k}+1)$. Thus we have the inequality

$$
\begin{equation*}
\mathrm{R}^{\prime}(\mathrm{K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1)) \leq \mathrm{R}(\mathrm{~K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1)) \tag{7}
\end{equation*}
$$

The following theorem is useful to determine the exact value of $\mathrm{R}^{\prime}(\mathrm{K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1))$.

Theorem 6 (Chartrand and Lesniak [5]) : For a positive integer $k$,

$$
\mathrm{R}(\mathrm{~K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1))= \begin{cases}2 \mathrm{k}+1, & \text { if } \mathrm{k} \text { is odd } \\ 2 \mathrm{k}+2, & \text { otherwise. }\end{cases}
$$

Lemma 5 : For a positive integer k,

$$
R^{\prime}(K(1, k+1), K(1, k+1))= \begin{cases}2 k+1, & \text { if } k \neq 2 \\ 6, & \text { if } k=2\end{cases}
$$

Proof : Consider the graph $H \cong K(k, k)$. Clearly $H$ is triangle-free, $\Delta(H)=k$ and $\Delta(\overline{\mathrm{H}})=\mathrm{k}-1$. Thus $\mathrm{R}^{\prime}(\mathrm{K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1)) \geq 2 \mathrm{k}+1$, for every positive integer k . Combining this with inequality (7), we have $\mathrm{R}^{\prime}(\mathrm{K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1))=2 \mathrm{k}+1$, whenever k is an odd positive integer. Similarly the graph $\mathrm{C}_{5}$ in conjunction with (7) implies that $R^{\prime}(K(1,3), K(1,3))=6$.

Henceforth we will assume that $k \geq 4$ and is even. We now prove that $\mathrm{R}^{\prime}(\mathrm{K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1)) \leq 2 \mathrm{k}+1$. Consider a traingle-free graph G of order $2 \mathrm{k}+1$ such that $\Delta(G) \leq k$. We will show that $\overline{\mathrm{G}}$ contains $\mathrm{K}(1, \mathrm{k}+1)$ as a subgraph. Suppose not, that is, $\Delta(\overline{\mathrm{G}}) \leq \mathrm{k}$. This implies that G is k -regular.

Let $u$ be a vertex of $G, A=N(u)$ and $B=V(G)-N[u]$. Since $G$ is triangle-free, $A$ is 0 -independent. Thus every vertex of $A$ has exactly $k-1$ neighbours in $B$ and hence the number of edges between $A$ and $B$ is $k(k-1)$. Thus $|E(G[B])|=\frac{k}{2}$. Firstly assume that $\Delta(\mathrm{G}[\mathrm{B}]) \geq 2$ and let $\mathrm{v} \in \mathrm{B}$ such that v has at least two neighbours in B . This implies that a neighbour $\mathrm{v}^{\prime}$ of v such that $\mathrm{v}^{\prime} \in \mathrm{A}$ has at most $\mathrm{k}-2$ neighbours in B , a contradiction. Thus $\Delta(G[B]) \leq 1$. Since $\varepsilon(G[B])=\frac{k}{2}$, it follows that $G[B]$ is isomorphic to a matching of size $\frac{k}{2}(\geq 2)$. Again this implies that every vertex of A has at most $\frac{k}{2}$ neighbours in B. This is a contradiction since $\frac{k}{2}<k-1$. This contradiction implies that $\overline{\mathrm{G}}$ contains $\mathrm{K}(1, \mathrm{k}+1)$ as a subgraph. Hence $\mathrm{R}^{\prime}(\mathrm{K}(1, \mathrm{k}+1), \mathrm{K}(1, \mathrm{k}+1)) \geq 2 \mathrm{k}+1$, for all even
integers $k \geq 4$. The graph $K(k, k)$ establishes the sharpness of the above inequality. This completes the proof of the lemma.

For notational convenience we denote $R^{\prime}(K(1, k+1), K(1, k+1))$, by $R^{\prime}$. From the definition of $R^{\prime}$ it follows that for any positive integer $t \leq R-1$, there exists a graph $H$ of order $t$ such that neither $H$ nor $\bar{H}$ contains a vertex of degree at least $k+1$. We refer to such a graph as a Ramsey graph and denote it by H[t]. The following lemma is easy and can be proved along the same lines as Lemma 6 in Achuthan et al. [1].

Lemma 6: Let $G$ be a triangle-free graph of order $p$ with $\chi_{k}(G)=1$. Then

$$
\chi_{\mathrm{k}}(\overline{\mathrm{G}}) \geq \frac{\mathrm{p}}{\mathrm{R}^{\prime}-1}
$$

We now present a sharp lower bound for $\chi_{k}(G) \cdot \chi_{k}(\overline{\mathrm{G}})$, where G is a trianglefree graph.

Theorem 7: Let G be a triangle-free graph of order $p$. Then

$$
\chi_{\mathrm{k}}(\mathrm{G}) \cdot \chi_{\mathrm{k}}(\overline{\mathrm{G}}) \geq\left\lceil\frac{\mathrm{p}}{\mathrm{R}^{\prime}-1}\right\rceil
$$

Moreover this bound is sharp.
Proof : Let $\chi_{k}(G)=m$ and consider a partition of $V(G)$ into $m$-independent sets $V_{1}, V_{2}, \ldots, V_{m}$ such that $\left|V_{1}\right|=\max _{i}\left|V_{i}\right| . \quad$ Since $\chi_{k}(\bar{G}) \geq \chi_{k}\left(\bar{G}\left[V_{I}\right]\right)$, it follows from Lemma 6 that

$$
\chi_{\mathrm{k}}(\overline{\mathrm{G}}) \geq \frac{\left|\mathrm{V}_{1}\right|}{\mathrm{R}^{\prime}-1} \geq \frac{\mathrm{p}}{\mathrm{~m}\left(\mathrm{R}^{\prime}-1\right)}
$$

Thus

$$
\chi_{\mathrm{k}}(\mathrm{G}) \cdot \chi_{\mathrm{k}}(\overline{\mathrm{G}}) \geq\left\lceil\frac{\mathrm{p}}{\mathrm{R}^{\prime}-1}\right\rceil=\lambda, \text { say } .
$$

To establish the sharpness we define a graph $G$, of order $p$, to be the disjoint union of $\lambda$ Ramsey graphs $\mathrm{H}_{1}, \mathrm{H}_{2}, \ldots, \mathrm{H}_{\lambda}$ where each $\mathrm{H}_{\mathrm{i}}$ has at most $\mathrm{R}-1$ vertices. This completes the proof of the theorem.

## ACKNOWLEDGEMENT:

The authors wish to thank the referee for his/her useful suggestions.
