#### Abstract

Let $\gamma_{b}(G)$ denote the broadcast domination number for a graph $G$. In [Discrete Applied Math. 154 (2006), 59-75], Dunbar et al. determined the value of $\gamma_{b}(G)$, where $G$ is the Cartesian product of two paths. In this paper, we evaluate the value of $\gamma_{b}(G)$, whenever $G$ is the strong product, the direct product and the lexicographic product of two paths.

## 1 Introduction

A radio station wishes to broadcast from towers of varying capacity so that the broadcast is heard by all intended recipients. Larger capacity towers can broadcast further, but will incur a higher associated cost (or transmission power, say in watts). To minimize this cost, the radio station has to place appropriate towers at carefully selected locations. The problem of choosing the locations and appropriate capacities of the towers can be rephrased as a broadcast domination problem. First introduced by Erwin [2] using the term cost domination in 2002, it is one of the many variations of domination. Observe that if we allow only capacity towers of distance 1 to be built in the broadcast scenario, we return to the domination problem. An overview of domination and its variants can be found in [3].

As in [2], we can model the problem by a graph whose vertices are the sections of the region and where an edge between two vertices indicates that the two sections are close to each other. Let $G$ be a connected simple graph with vertex set $V(G)$. The order of $G$ is the number of vertices in $G$. The distance between two vertices $u, v \in V(G)$, which we denote as $d(u, v)$, is the length of a shortest $u-v$ path in $G$. The eccentricity of a vertex $v \in V(G)$ is $e(v)=\max \{d(v, u) \mid u \in V(G)\}$. The radius and diameter of $G$ are defined as $\operatorname{rad}(G)=\min \{e(v) \mid v \in V(G)\}$ and $\operatorname{diam}(G)=\max \{e(v) \mid v \in V(G)\}$ respectively. A vertex $v \in V(G)$ is a central vertex if $e(v)=\operatorname{rad}(G)$.

[^0]A function $f: V(G) \rightarrow\{0,1, \ldots, \operatorname{diam}(G)\}$ is a broadcast if $f(v) \leq e(v)$ for every vertex $v \in V(G)$. We define $V_{f}^{+}=\{v \mid f(v)>0\}$, and say that every vertex in $V_{f}^{+}$is a broadcast vertex. We define the broadcast neighborhood of a broadcast vertex $v$ as $N_{f}[v]=\{u \mid d(u, v) \leq f(v)\}$, and say that each vertex $u \in N_{f}[v]$ hears the broadcast $f$ from vertex $v$. For a set $S \subseteq V_{f}^{+}$, we write $N_{f}[S]=\bigcup_{v \in S} N_{f}[v]$. If $N_{f}\left[V_{f}^{+}\right]=V(G)$, then $f$ is a dominating broadcast. We say that vertex $u$ is $f$-dominated by $S$ if $u \in$ $N_{f}[S]$. The cost of a broadcast $f$ is denoted as $\sigma(f)=\sum_{v \in V_{f}^{+}} f(v)$. A dominating broadcast $f$ with minimum cost is called a $\gamma_{b}$-broadcast of $G$, and the broadcast domination number for graph $G$, denoted by $\gamma_{b}(G)$, is defined as $\gamma_{b}(G)=\sigma(f)$, where $f$ is a $\gamma_{b}$-broadcast of $G$.

Let $G=G_{1} \star G_{2}$ be a graph product of two graphs $G_{1}$ and $G_{2}$, which has vertex set $V(G)=V\left(G_{1}\right) \times V\left(G_{2}\right)=\left\{\left(x_{1}, x_{2}\right) \mid x_{i} \in V\left(G_{i}\right)\right.$ for $\left.i=1,2\right\}$. There are four standard graph products, namely, the Cartesian, the strong, the direct, and the lexicographic product. Their respective graph products are denoted by $\square, \boxtimes, \times$, and - Two vertices $\left(u_{1}, u_{2}\right)$ and $\left(v_{1}, v_{2}\right)$ of $G$ are adjacent if and only if

1. $\star=\square$, and either $u_{1}=v_{1}$ and $u_{2} v_{2} \in E\left(G_{2}\right)$, or $u_{2}=v_{2}$ and $u_{1} v_{1} \in E\left(G_{1}\right)$,
2. $\star=\boxtimes$, and either $u_{1}=v_{1}$ and $u_{2} v_{2} \in E\left(G_{2}\right)$, or $u_{2}=v_{2}$ and $u_{1} v_{1} \in E\left(G_{1}\right)$, or $u_{1} v_{1} \in E\left(G_{1}\right)$ and $u_{2} v_{2} \in E\left(G_{2}\right)$,
3. $\star=\times, u_{1} v_{1} \in E\left(G_{1}\right)$ and $u_{2} v_{2} \in E\left(G_{2}\right)$, or
4. $\star=\bullet$, and either $u_{1} v_{1} \in E\left(G_{1}\right)$, or $u_{1}=v_{1}$ and $u_{2} v_{2} \in E\left(G_{2}\right)$.

The problem of determining the broadcast domination number for the Cartesian product of two graphs was first studied in [1]. Let $P_{n}$ denote a path of order $n$. In that paper, the authors found a closed formula for the special case where the two graphs are paths, i.e., a grid graph $P_{m} \square P_{n}$. We present their result as follows.

Theorem 1. [1] For $m \geq n \geq 2, \gamma_{b}\left(P_{m} \square P_{n}\right)=\operatorname{rad}\left(P_{m} \square P_{n}\right)=\left\lfloor\frac{m}{2}\right\rfloor+\left\lfloor\frac{n}{2}\right\rfloor$.
It is natural to consider the other three graph products. The remainder of this paper is organized as follows. In Section 2, we state some known results on broadcast domination, and give a property that is common to the strong, and the direct product of two paths. These results are used in Sections 3 to 5 to enumerate the broadcast domination number for the strong product, the direct product, and the lexicographic product of two paths respectively.

## 2 Background

A packing broadcast is a broadcast such that every vertex in $G$ hears from at most one broadcast vertex. An efficient broadcast is a dominating broadcast such that every vertex hears from one broadcast vertex only (possibly including itself). It is clear that every graph $G$ has an efficient broadcast, since we can broadcast from a central vertex with cost equal to $\operatorname{rad}(G)$. We also have the following stronger result.

Observation 2. [1] Every graph $G$ has a $\gamma_{b}$-broadcast which is efficient.
Observation 3. [2] For every positive integer $n, \gamma_{b}\left(P_{n}\right)=\left\lceil\frac{n}{3}\right\rceil$.
For any graph product, the vertices of $P_{m} \star P_{n}$ can be placed in a grid consisting of $m$ columns and $n$ rows. Let $f$ be a broadcast of $P_{m} \star P_{n}$. We say that a column (respectively row) is covered by $U \subseteq V_{f}^{+}$if at least one vertex in that column (respectively row) is $f$-dominated by $U$.

Observation 4. Let $G$ be either the graph $P_{m} \boxtimes P_{n}$ or a connected component of $P_{m} \times P_{n}$, where $m, n \geq 1$, and let $f$ be a broadcast on $G$. Then for any $U \subseteq V_{f}^{+}$, the number of rows (or columns) covered by $U$ is at most $\sum_{u \in U}(2 f(u)+1)$, which is less than or equal to $3 \cdot \sum_{u \in U} f(u)$.

## 3 Strong product of two paths

In this section, we evaluate the broadcast domination number for the graph $P_{m} \boxtimes P_{n}$, whose vertices are labeled as $(i, j)$ or $v_{(i, j)}$, where $i \leq m$ and $j \leq n$ are the column and row numbers respectively. Let $f$ be a broadcast on graph $P_{m} \boxtimes P_{n}$ with $m \geq n \geq 1$. Observe that for any $x \in V_{f}^{+}$, the induced subgraph $\left[N_{f}[x]\right]$ is also a strong product of two paths.

Lemma 5. Consider the graph $P_{m} \boxtimes P_{n}$, where $m \geq n \geq 1$. Then there exists a $\gamma_{b}$-broadcast $f$ such that $f(v) \geq\left\lceil\frac{n-1}{2}\right\rceil$ for all $v \in V_{f}^{+}$.

Proof. Let $W_{f}=\left\{v \in V_{f}^{+} \left\lvert\, 1 \leq f(v) \leq\left\lceil\frac{n-1}{2}\right\rceil-1\right.\right\}$. Suppose on the contrary that $W_{f}$ is nonempty. Consider vertex $w \in W_{f}$ with the largest $f(w)$. By Observation 4, since the number of rows covered by $\{w\}$ is at most $(2 \cdot f(w)+1) \leq\left(2 \cdot\left\lceil\frac{n-1}{2}\right\rceil-1\right)<n$, it follows that not all vertices in $V\left(P_{m} \boxtimes P_{n}\right)$ are $f$-dominated by $\{w\}$. Hence there exists a nonempty set $S \subseteq V_{f}^{+} \backslash\{w\}$ such that for any vertex $s \in S$, the induced subgraph $\left[N_{f}[s] \cup N_{f}[w]\right]$ is connected.

Let $t \in S$ be the vertex satisfying $f(t)=\max _{s \in S} f(s)$. We define $\alpha=2 \cdot(f(w)+$ $f(t)+1$ ), and consider any subgraph $A=P_{\alpha} \boxtimes P_{\min \{\alpha, n\}}$ with $N_{f}[w] \cup N_{f}[t] \subseteq V(A)$. If vertex $t$ is in $V_{f}^{+} \backslash W_{f}$, i.e., $f(t) \geq\left\lceil\frac{n-1}{2}\right\rceil$, we have $\alpha>2 \cdot(f(t)+1)>n$. Then for the subgraph $A=P_{\alpha} \boxtimes P_{n}$ (see Figure 1), not all vertices in $A$ are $f$-dominated by $\{w, t\}$. Since $f$ is a $\gamma_{b}$-broadcast, there must be another broadcast vertex in $A$, so that $\sum_{v \in V(A)} f(v) \geq f(t)+f(w)+1 \geq\left\lceil\frac{\alpha-1}{2}\right\rceil$.

Otherwise, vertex $t \in W_{f}$, i.e., $f(t) \leq f(w)$. By the maximality of $f(t)$, there exists another broadcast vertex in the subgraph $A=P_{\alpha} \boxtimes P_{\min \{\alpha, n\}}$ other than vertices $w$ and $t$ (see Figure 2). Hence we have $\sum_{v \in V(A)} f(v) \geq f(w)+f(t)+1 \geq\left\lceil\frac{\alpha-1}{2}\right\rceil$.

On the other hand, we can define a dominating broadcast $g$ as follows:

$$
g(v)= \begin{cases}\left\lceil\frac{\alpha-1}{2}\right\rceil & \text { if } v=a \text { is a central vertex in } A \\ 0 & \text { if } v \in V(A) \backslash\{a\} \\ f(v) & \text { if } v \in V\left(P_{m} \boxtimes P_{n}\right) \backslash V(A) .\end{cases}
$$

Figure 1: An illustration of vertex $t \in V_{f}^{+} \backslash W_{f}$ when $\alpha>n=8$.

Figure 2: An illustration of vertex $t \in W_{f}$ when $\alpha>n=8$.

To see why $g$ is dominating, we observe that vertex $a \in V(A)$ covers $(2 \cdot g(a)+1) \geq \alpha$ rows (or columns). Therefore if $\alpha \leq n$, we have $V(A)=V\left(P_{\alpha} \boxtimes P_{\alpha}\right) \subseteq N_{g}[a]$. Otherwise $\alpha>n$, and $V(A)=V\left(P_{\alpha} \boxtimes P_{n}\right) \subseteq N_{g}[a]$. In fact, since $f$ is a $\gamma_{b}$-broadcast and $\sigma(f)=\sigma(g), g$ is therefore a $\gamma_{b}$-broadcast.

Finally, we consider the set $W_{g}=\left\{v \in V_{g}^{+} \left\lvert\, 1 \leq g(v) \leq\left\lceil\frac{n-1}{2}\right\rceil-1\right.\right\}$. For $\alpha \leq n,\left|W_{g}\right|<\left|W_{f}\right|$. This is because vertex $t$ is in $W_{f}$, which implies that $W_{g} \subset$ $\left(W_{f} \cup\{a\}\right) \backslash\{w, t\}$. The same inequality holds for $\alpha>n$ since $g(a)=\left\lceil\frac{\alpha-1}{2}\right\rceil>\left\lceil\frac{n-1}{2}\right\rceil$, i.e., vertex $a$ is not in $W_{g}$. This implies that $W_{g} \subset\left(W_{f} \cup\{a\}\right) \backslash\{w\}$. By applying the above procedure repeatedly for a finite number of times, we obtain a $\gamma_{b}$-broadcast (say $h$ ) such that $h(v) \geq\left\lceil\frac{n-1}{2}\right\rceil$ for all $v \in V_{h}^{+}$.

Lemma 6. For any graph $P_{m} \boxtimes P_{n}$ with $m \geq n \geq 1$, there exists a $\gamma_{b}$-broadcast $f$ such that $f$ is efficient and $f(v) \geq\left\lceil\frac{n-1}{2}\right\rceil$ for all $v \in V_{f}^{+}$.

Proof. By Observation 2, there exists a $\gamma_{b}$-broadcast $f$ which is efficient. If there is a vertex $v \in V_{f}^{+}$with $f(v)<\left\lceil\frac{n-1}{2}\right\rceil$, we apply the steps described in the proof for Lemma 5 , so that the result follows.

Lemma 7. For $m \geq n \geq 2, \gamma_{b}\left(P_{m} \boxtimes P_{n}\right) \geq\left\lceil\frac{m-\left\lfloor\frac{m}{p}\right\rfloor}{2}\right\rceil$, where $p=\left(2 \cdot\left\lceil\frac{n-1}{2}\right\rceil+1\right)$ is the smallest odd integer greater than or equal to $n$.

Proof. By Lemma 6, the graph $P_{m} \boxtimes P_{n}$ has an efficient $\gamma_{b}$-broadcast $f: V \rightarrow$ $\left\{0,\left\lceil\frac{n-1}{2}\right\rceil,\left\lceil\frac{n-1}{2}\right\rceil+1, \ldots, \operatorname{diam}\left(P_{m} \boxtimes P_{n}\right)\right\}$. We define a broadcast $g$ as follows:

$$
g(v)= \begin{cases}\left\lceil\frac{n-1}{2}\right\rceil & \text { if } f(v) \geq\left\lceil\frac{n-1}{2}\right\rceil \\ 0 & \text { otherwise }\end{cases}
$$

Since $g$ is a packing broadcast (but not necessarily dominating), we have $\sum_{v \in V_{g}^{+}}(2$. $g(v)+1) \leq m$, so that $\left|V_{f}^{+}\right|=\left|V_{g}^{+}\right| \leq\left\lfloor\frac{m}{2 \cdot\left\lceil\frac{n-1}{2}\right\rceil+1}\right\rfloor\left\lfloor\frac{m}{p}\right\rfloor$. Finally, as $f$ is a dominating broadcast, we have $\sum_{v \in V_{f}^{+}}(2 \cdot f(v)+1) \geq m$, or equivalently, $\gamma_{b}\left(P_{m} \boxtimes P_{n}\right)=$ $\sum_{v \in V_{f}^{+}} f(v) \geq\left\lceil\frac{m-\left|V_{f}^{+}\right|}{2}\right\rceil \geq\left\lceil\frac{m-\left\lfloor\frac{m}{p}\right\rfloor}{2}\right\rceil$.

In the following theorem, we give the broadcast domination number for the graph $P_{m} \boxtimes P_{n}$. Roughly speaking, the proof involves a construction of a low cost broadcast, whose broadcast vertices lie in the middle of the columns, and are separated by a distance that is roughly $n$. Except for one of the broadcast vertices, which has a larger broadcast capacity in order to broadcast to vertices in the $m^{\text {th }}$ column of the graph, all the other broadcast vertices have the same broadcast capacity.

Theorem 8. For the graph $P_{m} \boxtimes P_{n}$ with $m \geq n \geq 1$,

$$
\gamma_{b}\left(P_{m} \boxtimes P_{n}\right)=\left\lceil\frac{1}{2} \cdot\left(m-\left\lfloor\frac{m}{\max \{p, 3\}}\right\rfloor\right)\right\rceil,
$$

where $p=\left(2 \cdot\left\lceil\frac{n-1}{2}\right\rceil+1\right)$.
Proof. For $n=1$, we have from Observation 3 that $\gamma_{b}\left(P_{m} \boxtimes P_{1}\right)=\gamma_{b}\left(P_{m}\right)=\left\lceil\frac{m}{3}\right\rceil=$ $\left\lceil\frac{m-\left\lfloor\frac{m}{3}\right\rfloor}{2}\right\rceil$. For $n \geq 2$, we define a broadcast $f$ as follows:

$$
f\left(v_{(i, j)}\right)=\left\{\begin{array}{cl}
\left\lceil\frac{n-1}{2}\right\rceil & \text { if } i=\left(\left\lceil\frac{n+1}{2}\right\rceil+k \cdot p\right) \text { and } j=\left\lceil\frac{n}{2}\right\rceil \\
& \text { where } k=0,1, \ldots,\left\lfloor\frac{m}{p}\right\rfloor-2 \\
\left\lceil\frac{m-p \cdot\left\lfloor\frac{m}{p}\right\rfloor+p-1}{2}\right\rceil & \text { if } i=m-\left\lceil\frac{m-p \cdot\left\lfloor\frac{m}{p}\right\rfloor+p-1}{2}\right\rceil \text { and } j=\left\lceil\frac{n}{2}\right\rceil \\
0 & \text { otherwise. }
\end{array}\right.
$$

It can be shown that $f$ is a dominating broadcast. Also since $\left\lceil\frac{n-1}{2}\right\rceil=\frac{p-1}{2}, \sigma(f)=$ $\left(\left\lfloor\frac{m}{p}\right\rfloor-1\right) \cdot\left\lceil\frac{n-1}{2}\right\rceil+\left\lceil\frac{m-p \cdot\left\lfloor\frac{m}{p}\right\rfloor+p-1}{2}\right\rceil \leq \frac{p \cdot\left\lfloor\frac{m}{p}\right\rfloor-p-\left\lfloor\frac{m}{p}\right\rfloor+1}{2}+\frac{m-p \cdot\left\lfloor\frac{m}{p}\right\rfloor+p-1}{2}+\frac{1}{2} \leq\left\lfloor\frac{m-\left\lfloor\frac{m}{p}\right\rfloor}{2}+\frac{1}{2}\right\rfloor=$ $\left\lceil\frac{m-\left\lfloor\frac{m}{p}\right\rfloor}{2}\right\rceil$. Then by Lemma 7, we get the required result.

## 4 Direct product of two paths

In this section, we determine the broadcast domination number for graph $P_{m} \times P_{n}$, whose vertices are labeled as $(i, j)$ or $v_{(i, j)}$, where $i \leq m$ and $j \leq n$ are the column and row numbers respectively. Observe that $P_{m} \times P_{n}$ consists of two isomorphic connected components if either $m$ or $n$ is even. Otherwise it has two non-isomorphic connected components [4]. We call the component of $P_{m} \times P_{n}$ containing $v_{(1,1)}$ the even component, and the other component the odd component.

Lemma 9. For any component of graph $P_{m} \times P_{n}$ with $m \geq n \geq 1$, there exists a $\gamma_{b}$-broadcast $f$ such that
(i) $f$ is efficient,
(ii) $f(v) \geq\left\lceil\frac{n-1}{2}\right\rceil$ for all $v \in V_{f}^{+}$,
(iii) $f\left(v_{(i, j)}\right) \geq\left\lceil\frac{n}{2}\right\rceil$ for all $v_{(i, j)} \in V_{f}^{+}$, where $j \neq\left\lceil\frac{n-1}{2}\right\rceil$, and
(iv) each column of the graph has at most one broadcast vertex.

Proof. The proofs for (i) and (ii) are similar to that of Lemmas 6 and 5 respectively, and are omitted. For (iii), since $\left\lceil\frac{n-1}{2}\right\rceil=\left\lceil\frac{n}{2}\right\rceil$ when $n$ is even, it remains to show that (iii) holds for odd values of $n$. Suppose on the contrary that (iii) is false for some odd value of $n$. Then we can find a vertex $v_{(a, b)}$ with $b \neq\left\lceil\frac{n-1}{2}\right\rceil$ such that $f\left(v_{(a, b)}\right) \leq \frac{n-1}{2}$. Note that (ii) implies $f\left(v_{(a, b)}\right)=\frac{n-1}{2}$, so there is at least one vertex among all the vertices in columns $a-1, a$ and $a+1$ that do not hear the broadcast from $v_{(a, b)}$. Since $f$ is dominating, there exists a broadcast vertex $u$ near the $a^{\text {th }}$ column. By (ii), we have $f(u) \geq\left\lceil\frac{n-1}{2}\right\rceil$. However this contradicts our assumption in (i) that $f$ is efficient. Hence (iii) must be true (see Figure 3). Finally, (iv) follows from (ii) and (iii).

Figure 3: Illustration of proof for Lemma 9(iii) when $n=7$ is odd.

We will now proceed to consider each of the components.
Even component with $n$ odd:
For $m \geq n \geq 2$ with $n$ odd, let graph $A$ be the even component of $P_{m} \times P_{n}$. Since $v_{(1,1)}$ is in the even component, the number of vertices in the first row is $\left\lceil\frac{m}{2}\right\rceil$. Based on this fact, we have the following lemma.
Lemma 10. $\gamma_{b}(A) \geq\left\lceil\frac{m-k}{2}\right\rceil$, where $k=\left\lfloor\frac{2 \cdot\left\lceil\frac{m}{2}\right\rceil}{n+1}\right\rfloor$.
Proof. By Lemma 9(i)-(ii), graph $A$ has an efficient $\gamma_{b}$-broadcast $f: V \rightarrow\left\{0,\left\lceil\frac{n-1}{2}\right\rceil\right.$, $\left.\left\lceil\frac{n-1}{2}\right\rceil+1, \ldots, \operatorname{diam}(A)\right\}$. Let $S=\left\{a \mid v_{(a, b)} \in V_{f}^{+}\right\}$be the column numbers that has one broadcast vertex. We define a broadcast $g$ as follows:

$$
g\left(v_{(i, j)}\right)= \begin{cases}\left\lceil\frac{n-1}{2}\right\rceil & \text { if } i=a \text { or } a+1, \text { and } j=\left\lceil\frac{n+1}{2}\right\rceil, \text { where } a \in S \\ 0 & \text { otherwise. }\end{cases}
$$

Note that vertices $\left(a,\left\lceil\frac{n+1}{2}\right\rceil\right)$ and $\left(a+1,\left\lceil\frac{n+1}{2}\right\rceil\right)$ cannot exist simultaneously in $V(A)$. Therefore $\left|V_{f}^{+}\right|=\left|V_{g}^{+}\right|$, and it is clear that $g$ is a packing broadcast, but not necessarily a dominating broadcast.

Let $V_{1}(A)$ be the set of vertices in the first row of graph $A$. Since we have $\left|N_{g}(v) \cap V_{1}(A)\right|=\frac{n+1}{2}$ for each $v \in V_{g}^{+}$, it follows from the definition of packing broadcast that $\left|V_{f}^{+}\right|=\left|V_{g}^{+}\right| \leq\left\lfloor\frac{\left\lceil\frac{m}{2}\right\rceil}{\frac{n+1}{2}}\right\rfloor=k$. Finally, as $f$ is a dominating broadcast, we have $\sum_{v \in V_{f}^{+}}(2 \cdot f(v)+1) \geq m$, or equivalently, $\gamma_{b}(A)=\sum_{v \in V_{f}^{+}} f(v) \geq\left\lceil\frac{m-\left|V_{f}^{+}\right|}{2}\right\rceil \geq$ $\left\lceil\frac{m-k}{2}\right\rceil$.

Theorem 11. $\gamma_{b}(A)=\left\lceil\frac{m-k}{2}\right\rceil$, where $k=\left\lfloor\frac{2 \cdot\left\lceil\frac{m}{2}\right\rceil}{n+1}\right\rfloor$.
Proof. The proof is similar to that of Theorem 8. We define a broadcast $f$ as follows:

$$
f\left(v_{(i, j)}\right)=\left\{\begin{array}{cc}
\left\lceil\frac{n+(-1)^{q}}{2}\right\rceil & \text { if } i=(2 q-1) \cdot\left\lceil\frac{n+1}{2}\right\rceil \text { and } j=\left\lceil\frac{n+1}{2}\right\rceil, \\
\text { where } q=1,2, \ldots, k-1 \\
\left\lceil\frac{m-k}{2}\right\rceil-\left\lfloor\frac{n(k-1)}{2}\right\rfloor & \text { if } i=m-\left\lceil\frac{m-k}{2}\right\rceil+\left\lfloor\frac{n(k-1)}{2}\right\rfloor, \\
\text { and } j=\left\lceil\frac{n+1}{2}\right\rceil-1 \text { or }\left\lceil\frac{n+1}{2}\right\rceil \\
0 & \text { otherwise. }
\end{array}\right.
$$

It can be shown that all the broadcast vertices belong to $V(A)$, and that $f$ is dominating. Also since $n$ is odd, we have $\left\lfloor\frac{k-1}{2}\right\rfloor \cdot\left\lceil\frac{n+1}{2}\right\rceil+\left\lceil\frac{k-1}{2}\right\rceil \cdot\left\lceil\frac{n-1}{2}\right\rceil=\frac{n(k-1)}{2}$ when $k$ is odd. Similarly we have $\left\lfloor\frac{k-1}{2}\right\rfloor \cdot\left\lceil\frac{n+1}{2}\right\rceil+\left\lceil\frac{k-1}{2}\right\rceil \cdot\left\lceil\frac{n-1}{2}\right\rceil=\frac{k-2}{2} \cdot \frac{n+1}{2}+\frac{k}{2} \cdot \frac{n-1}{2}=\frac{n(k-1)-1}{2}$ when $k$ is even.

Therefore $\sigma(f)=\left\lceil\frac{m-k}{2}\right\rceil-\left\lfloor\frac{n(k-1)}{2}\right\rfloor+\left\lfloor\frac{k-1}{2}\right\rfloor \cdot\left\lceil\frac{n+1}{2}\right\rceil+\left\lceil\frac{k-1}{2}\right\rceil \cdot\left\lceil\frac{n-1}{2}\right\rceil \leq\left\lceil\frac{m-k}{2}\right\rceil$. Then by Lemma 10, we get the desired result.

Odd component with $n$ odd:
For $m \geq n \geq 2$ with $n$ odd, let graph $B$ be the odd component of $P_{m} \times P_{n}$. Since $v_{(1,1)}$ is not in the odd component, the number of vertices in the first row is $\left\lfloor\frac{m}{2}\right\rfloor$. Based on this fact, we have the following lemma.

Lemma 12. $\gamma_{b}(B) \geq\left\lceil\frac{m-k}{2}\right\rceil$, where $k=\left\lfloor\frac{m}{n+1}\right\rfloor$.
Proof. The proof is similar to that of Lemma 10, and thus omitted.
Theorem 13. $\gamma_{b}(B)=\left\lceil\frac{m-k}{2}\right\rceil$, where $k=\left\lfloor\frac{m}{n+1}\right\rfloor$.
Proof. The proof is similar to that of Theorem 11. We define a broadcast $f$ as follows:

$$
f\left(v_{(i, j)}\right)=\left\{\begin{array}{cc}
\left\lceil\frac{n+(-1)^{q+1}}{2}\right\rceil & \text { if }(i, j)=\left((2 q-1)\left\lceil\frac{n+1}{2}\right\rceil+1,\left\lceil\frac{n+1}{2}\right\rceil\right) \\
\text { where } q=1,2, \ldots, k-1 \\
\left\lceil\frac{m-k}{2}\right\rceil-\left\lceil\frac{n(k-1)}{2}\right\rceil & \text { if } i=m-\left\lceil\frac{m-k}{2}\right\rceil\left\lceil\left\lceil\frac{n(k-1)}{2}\right\rceil,\right. \\
0 & \text { and } j=\left\lceil\frac{n+1}{2}\right\rceil-1 \text { or }\left\lceil\frac{n+1}{2}\right\rceil \\
0 & \text { otherwise. }
\end{array}\right.
$$

It can be shown that all the broadcast vertices belong to $V(B)$, and that $f$ is dominating. Also since $n$ is odd, by considering the cases when $k$ is odd and even separately, $\sigma(f)=\left\lceil\frac{m-k}{2}\right\rceil-\left\lceil\frac{n(k-1)}{2}\right\rceil+\left\lceil\frac{k-1}{2}\right\rceil \cdot\left\lceil\frac{n+1}{2}\right\rceil+\left\lfloor\frac{k-1}{2}\right\rfloor \cdot\left\lceil\frac{n-1}{2}\right\rceil \leq\left\lceil\frac{m-k}{2}\right\rceil$. Then by Lemma 12, we get the desired result.
$\underline{\text { Even or odd component with } n \text { even: }}$
When $n$ is even, the even component is isomorphic to the odd component. Hence we consider only the even component. Coincidentally, the following proofs are almost identical to that of the strong product of two paths. For $m \geq n \geq 2$ with $n$ even, let graph $C$ be the even component of $P_{m} \times P_{n}$.

Lemma 14. $\gamma_{b}(C) \geq\left\lceil\frac{m-k}{2}\right\rceil$, where $k=\left\lfloor\frac{m}{n+1}\right\rfloor$.
Proof. The proof in Lemma 7 applies here. Notice that $p=\left(2 \cdot\left\lceil\frac{n-1}{2}\right\rceil+1\right)$ can be simplified to $p=n+1$.

Theorem 15. $\gamma_{b}(C)=\left\lceil\frac{m-k}{2}\right\rceil$, where $k=\left\lfloor\frac{m}{n+1}\right\rfloor$.
Proof. Let $p=\left(2 \cdot\left\lceil\frac{n-1}{2}\right\rceil+1\right)=n+1$. We define a broadcast $f$ as follows:

$$
f\left(v_{(i, j)}\right)=\left\{\begin{array}{cc}
\left\lceil\frac{n-1}{2}\right\rceil & \text { if } i=\left(\left\lceil\frac{n+1}{2}\right\rceil+r \cdot p\right) \text { and } j=\left\lceil\frac{n+(-1)^{r}}{2}\right\rceil, \\
& \text { where } r=0,1, \ldots,\left\lfloor\frac{m}{p}\right\rfloor-2 \\
\left\lceil\frac{m-p \cdot\left\lfloor\frac{m}{p}\right\rfloor+p-1}{2}\right\rceil & \text { if } i=m-\left\lceil\frac{m-p \cdot\left\lfloor\frac{m}{p}\right\rfloor+p-1}{2}\right\rceil, \\
& \text { and } j=\left\lceil\frac{n-1}{2}\right\rceil \text { or }\left\lceil\frac{n+1}{2}\right\rceil \\
0 & \text { otherwise. }
\end{array}\right.
$$

It can be shown that all the broadcast vertices belong to $V(C)$, and that $f$ is a dominating broadcast with cost $\sigma(f) \leq\left\lceil\frac{m-k}{2}\right\rceil$. Therefore by Lemma 14, we have the desired result.

We now give a unified formula for the broadcast domination number of graph $P_{m} \times P_{n}$.

Corollary 16. For the graph $P_{m} \times P_{n}$ with $m \geq n \geq 1$,

$$
\gamma_{b}\left(P_{m} \times P_{n}\right)=\left\{\begin{array}{cl}
m & \text { if } n=1 \\
n \cdot\left(\frac{m+1}{n+1}\right) & \text { if } n \geq 2, m, n \text { both odd with } \frac{m+1}{n+1} \text { integer } \\
2 \cdot\left\lceil\frac{m-\left\lfloor\frac{m}{n+1}\right\rfloor}{2}\right\rceil & \text { otherwise. }
\end{array}\right.
$$

Proof. Use Observation 3, Theorems 11, 13, and 15, and then simplify to get the required result.

## 5 Lexicographic product of two paths

In this section, we determine the broadcast domination number for graph $P_{m} \bullet P_{n}$, whose vertices are labeled as $(i, j)$ or $v_{(i, j)}$, where $i \leq m$ and $j \leq n$ are the column
and row numbers respectively. Note that generally $G_{1} \bullet G_{2}$ is not isomorphic to $G_{2} \bullet G_{1}$. Let $f$ be a broadcast on graph $P_{m} \bullet P_{n}$. Observe that for any $x \in V_{f}^{+}$with $f(x) \geq 2$, the induced subgraph $\left[N_{f}[x]\right]$ is also a lexicographic product of two paths. Furthermore, if vertex $v$ is $f$-dominated by $\{x\}$, then all vertices in the same column as vertex $v$ are $f$-dominated by $\{x\}$.

The following observation is similar to that of Observation 4.
Observation 17. Let $f$ be a broadcast on $P_{m} \bullet P_{n}$, where $m, n \geq 1$. Then for any $U \subseteq V_{f}^{+}$, the number of columns covered by $U$ is at most $\sum_{u \in U}(2 f(u)+1)$, which is less than or equal to $3 \cdot \sum_{u \in U} f(u)$.

In the following lemma, we consider the graph $P_{m} \bullet P_{n}$ with either $m \leq 2$ or $n \leq 3$.

Lemma 18. Consider the graph $P_{m} \bullet P_{n}$.
(i) If either $m=1$ or $n \leq 3$, then $\gamma_{b}\left(P_{m} \bullet P_{n}\right)=\left\lceil\frac{\max \{m, n\}}{3}\right\rceil$.
(ii) If $n \geq 4$, then $\gamma_{b}\left(P_{2} \bullet P_{n}\right)=2$.

Proof. We will only prove (i), as the proof for (ii) is obvious. If either $m=1$ or $n=1$, then $\gamma_{b}\left(P_{m} \bullet P_{n}\right)=\gamma_{b}\left(P_{\max \{m, n\}}\right)=\left\lceil\frac{\max \{m, n\}}{3}\right\rceil$ by Observation 3. Otherwise, $n \in\{2,3\}$. Let $f$ be a $\gamma_{b}$-broadcast on $P_{m} \bullet P_{n}$. By Observation 17, $3 \cdot \sum_{u \in V_{f}^{+}} f(u) \geq$ $m$. Hence $\gamma_{b}\left(P_{m} \bullet P_{n}\right)=\sum_{u \in V_{f}^{+}} f(u) \geq\left\lceil\frac{m}{3}\right\rceil$. On the other hand, it can be verified that the following broadcast on $P_{m} \bullet P_{n}$ is dominating.

$$
g\left(v_{(p, q)}\right)= \begin{cases}1 & \text { if }(p, q)=(3 k-1,2), \text { where } k=1,2, \ldots,\left\lfloor\frac{m}{3}\right\rfloor \\ \left\lceil\frac{m}{3}-\left\lfloor\frac{m}{3}\right\rfloor\right\rceil & \text { if }(p, q)=(m, 2) \\ 0 & \text { otherwise }\end{cases}
$$

Furthermore when $m \equiv 0(\bmod 3), \gamma_{b}\left(P_{m} \bullet P_{n}\right) \leq \sum_{v \in V_{s}^{+}} g(v)=\frac{m}{3}=\left\lceil\frac{m}{3}\right\rceil$. Similarly when $m \not \equiv 0(\bmod 3), \gamma_{b}\left(P_{m} \bullet P_{n}\right) \leq \sum_{v \in V_{g}^{+}} g(v) \leq\left\lfloor\frac{m}{3}\right\rfloor+1=\left\lceil\frac{m}{3}\right\rceil$. Hence $g$ is a $\gamma_{b}$-broadcast with cost equal to $\left\lceil\frac{m}{3}\right\rceil$.

For the graph $P_{m} \bullet P_{n}$ with $m \geq 3$ and $n \geq 4$, we shall examine vertices in the bottom and top rows.

Observation 19. Let $f$ be a broadcast on $P_{m} \bullet P_{n}$, where $m \geq 3$ and $n \geq 4$. Let $B=\left\{v_{(i, 1)} \mid 1 \leq i \leq m\right\}$ and $T=\left\{v_{(i, n)} \mid 1 \leq i \leq m\right\}$. Then for any $U \subseteq V_{f}^{+}$, the number of $f$-dominated vertices in $B \cup T$ is at most $5 \sum_{u \in U} f(u)$.

Proof. Consider any vertex $v \in V_{f}^{+}$. If $f(v)=1$, then $\left|N_{f}[v] \cap(B \cup T)\right| \leq 5$ as at most three vertices in $B \cup T$ hear the broadcast $f$ from vertex $v$. For $f(v)=k \geq 2$, since $N_{f}[v]$ covers at most $(2 k+1)$ columns, we have $\left|N_{f}[v] \cap(B \cup T)\right| \leq 2(2 k+1) \leq 5 k$.

Lemma 20. For $m \geq 3$ and $n \geq 4, \gamma_{b}\left(P_{m} \bullet P_{n}\right)=\left\lceil\frac{2 m}{5}\right\rceil$.
Proof. Let $f$ be a $\gamma_{b}$-broadcast, and let $B$ and $T$ be as defined earlier. Then all vertices in $B \cup T$ hear the broadcast $f$. Hence by Observation 19, $2 m=|B \cup T| \leq$ $5 \sum_{v \in V_{f}^{+}} f(v)=5 \gamma_{b}\left(P_{m} \bullet P_{n}\right)$. It follows that $\gamma_{b}\left(P_{m} \bullet P_{n}\right) \geq\left\lceil\frac{2 m}{5}\right\rceil$.

On the other hand, the broadcast defined by

$$
\begin{array}{rlll}
f\left(v_{(5 i-2,1)}\right) & =2 & i=1,2, \ldots,\left\lceil\frac{m}{5}\right\rceil & \text { for } m \equiv 0,3,4 \\
(\bmod 5) \\
f\left(v_{(4,1)}\right)=3, f\left(v_{(5 i, 1)}\right) & =2 & i=2,3, \ldots,\left\lceil\frac{m}{5}\right\rceil & \text { for } m \equiv 1,2
\end{array} \quad(\bmod 5)
$$

is a dominating broadcast of cost $\left\lceil\frac{2 m}{5}\right\rceil$. The result follows.
Theorem 21. For the graph $P_{m} \bullet P_{n}$,

$$
\gamma_{b}\left(P_{m} \bullet P_{n}\right)= \begin{cases}\max \left\{\left\lceil\frac{m}{3}\right\rceil,\left\lceil\frac{n}{3}\right\rceil\right\} & \text { if } m=1 \text { or } n \in\{1,2,3\} \\ \max \left\{\left\lceil\frac{2 m}{5}\right\rceil, 2\right\} & \text { if } m \geq 2 \text { and } n \geq 4 .\end{cases}
$$

Proof. Result follows from Lemmas 18 and 20.
To end this paper, we would like to present here some open problems for future research. The value of $\gamma_{b}(G)$, where $G$ is the Cartesian product of two cycles, has been enumerated in [5].
Problem 1. Evaluate the value of $\gamma_{b}(G)$, where $G$ is the strong product, the direct product or the lexicographic product of two cycles.
Problem 2. Evaluate the value of $\gamma_{b}(G)$, where $G$ is the Cartesian product, the strong product, the direct product or the lexicographic product of a path and a cycle.

## Acknowledgments

We would like to express our sincere thanks to the referees for their useful comments and suggestions.
