**Abstract**

An infinite family of $(q^2 + q + 1)$-ovoids of $\mathcal{Q}^+(7, q)$, $q \equiv 1 \pmod{3}$, admitting the group $\text{PGL}(3, q)$, is constructed. The main tool is the general theory of generalized hexagons.

1 **Introduction**

Let $q$ be a prime power, $\mathbb{F}_q$ the finite field of order $q$, and $V$ a finite dimensional vector space over $\mathbb{F}_q$. Let $f$ be a non-degenerate reflexive sesquilinear form or a non-singular quadratic form on $V$. The finite classical polar space $\mathcal{S}$ associated with $(V, f)$ is the geometry consisting of the totally singular or totally isotropic subspaces with respect to $f$ of the ambient projective space $\text{PG}(V)$, according to whether $f$ is a quadratic or sesquilinear form. The totally singular or totally isotropic one-dimensional subspaces are the points of $\mathcal{S}$, and the collection of all the points of $\mathcal{S}$ will be denoted by $\mathcal{P}$. The totally singular or totally isotropic subspaces of maximum dimension are called the generators of $\mathcal{S}$. The rank of $\mathcal{S}$ is the vector space dimension of its generators. A finite classical polar space of rank 2 is a point-line geometry, and is also called a *finite generalized quadrangle*. Polar spaces over finite fields are very interesting geometric structures because they possess large automorphism groups, namely the finite classical groups. In this context it is natural to investigate combinatorial objects embedded in polar spaces admitting a fairly large group. Here, along these lines, we are interested in particular substructures of polar spaces called $m$-ovoids, having many symmetries.
The notion of an $m$-ovoid came from “ovoids” of the projective space PG$(3, q)$. It was first defined in generalized quadrangles by Thas [20], and was later extended naturally to finite classical polar spaces of higher rank in the work of Shult and Thas [19], where an $m$-ovoid was defined to be a set of points having exactly $m$ points in common with each generator (a 1-ovoid is simply called an ovoid). In [2] the authors found that $m$-ovoids and tight sets of generalized quadrangles share the property that they have two intersection numbers with respect to perps of points (one for points in the set and the other for points not in the set), and they coined such sets intriguing. Here, the perp of a point $P$ is the set of the points of the generalized quadrangle that are collinear with $P$. In a subsequent paper [1], the authors extended the concept of an intriguing set to finite classical polar spaces of higher rank. Over the past two decades, intriguing sets have been extensively studied and they are known to have close connection to many geometric/combinatorial objects, such as translation planes, strongly regular graphs, two-weight codes, Boolean degree one functions, completely regular codes of strength 0 and covering radius one, and Cameron-Liebler line classes. We refer the reader to [3, 6, 11–14, 17, 18] for some recent results on intriguing sets of polar spaces.

There are some straightforward methods for constructing $m$-ovoids. Let $S$ be a polar space of rank $r$ over the field $\mathbb{F}_q$. As an example, the whole point set of $S$ is a $\frac{q^r-1}{q-1}$-ovoid. Let $A$ and $B$ be an $m$-ovoid and $n$-ovoid of $S$, respectively. If $A \subseteq B$, then $B \setminus A$ is an $(m - n)$-ovoid. In particular, the complement of $A$ is a $(\frac{q^r-1}{q-1}-m)$-ovoid. Dually, if $A$ and $B$ are disjoint, then $A \cup B$ is an $(m + n)$-ovoid.

In hyperbolic polar spaces $S = \mathcal{Q}^+(2r - 1, q)$, there are some less straightforward ways to construct $m$-ovoids. First of all, a non-degenerate hyperplane section of $S$ which is an embedded $\mathcal{Q}(2r - 2, q)$ is a $\frac{q^{2r-2}-1}{q-1}$-ovoid, and an $m$-ovoid of the embedded $\mathcal{Q}(2r - 2, q)$ is also an $m$-ovoid of $S$. Furthermore, new $m$-ovoids can be obtained from old ones by derivation (see [16]). There are other constructions in hyperbolic spaces of different ranks. If $r = 2$, then $S = \mathcal{Q}^+(3, q)$ which is a grid. It is easy to see that $\mathcal{Q}^+(3, q)$ can be partitioned into ovoids and so $m$-ovoids exist for all possible $m$. If $r = 3$, then $S = \mathcal{Q}^+(5, q)$ and an ovoid of $\mathcal{Q}^+(5, q)$ is equivalent to a spread of PG$(3, q)$ under the Klein correspondence. It is known that the lines of PG$(3, q)$ can be partitioned into spreads (such a partition is called a packing of PG$(3, q)$) [8]. This means that $m$-ovoids of $\mathcal{Q}^+(5, q)$ exist for all possible $m$. The situation is much more different when $r$ is greater than 3 and only a few results are known. We will be focusing on $\mathcal{Q}^+(7, q)$ in this work. It is known that ovoids exist in $\mathcal{Q}^+(7, q)$ when $q$ is even, an odd prime or $q \equiv 0 \pmod{2}$ (mod 3) [15, Table 7.3]. As mentioned above, $m$-ovoids of $\mathcal{Q}(6, q)$ are $m$-ovoids of $\mathcal{Q}^+(7, q)$. Constructions of $m$-ovoids of $\mathcal{Q}(6, q)$ can be found in [1, 5, 18]. There are further known $m$-ovoids of $\mathcal{Q}^+(7, q)$ which we present in Section 4 when dealing with the isomorphism issue.

In this paper, we construct an infinite family of $(q^2 + q + 1)$-ovoids of $\mathcal{Q}^+(7, q)$, $q \equiv 1 \pmod{3}$, admitting PGL$(3, q)$ as an automorphism group and not contained in a hyperplane section. The promised $(q^2 + q + 1)$-ovoid will be described as a set $O$ of points covered by the planes spanned by two incident lines of a thin hexagon embedded in $\mathcal{Q}^+(7, q)$. The advantage is that in this way one can apply basic results from the theory of generalized hexagons. The properties of the hexagon that will be needed are achieved in Section 2.

In Section 3 we define the set $O$ precisely and show that it is a $(q^2 + q + 1)$-ovoid. Finally, we show that our example is new in Section 4, and a problem is posed in the end.
For the rest of this paper, we shall use the following definition of \( m \)-ovoids rather than the one given by Shult and Thas as mentioned in the second paragraph.

**Definition 1.1.** Let \( P \) be the point set of \( Q^+(2r - 1, q) \). A subset \( M \) of \( P \) is called an \( m \)-ovoid if there is an integer \( m > 0 \) such that for all \( P \in P \),

\[
|P^\perp \cap M| = \begin{cases} m\theta_r - \theta_{r-1} + 1, & \text{if } P \in M, \\ m\theta_r, & \text{if } P \notin M, \end{cases} \tag{1.1}
\]

where \( \theta_r = q^{r-1} + 1 \) and \( P^\perp \) is the set of points in \( Q^+(2r - 1, q) \) that are collinear with \( P \).

## 2 Preliminaries

Let \( p \) be a prime, and let \( q = p^e \), where \( e \geq 1 \) is an integer. The multiplicative group of \( \mathbb{F}_q \) will be denoted by \( \mathbb{F}_q^* \). For an integer \( n \geq 1 \), the relative trace \( \text{Tr}_{q^n/q} \) from \( \mathbb{F}_{q^n} \) to \( \mathbb{F}_q \) is defined by

\[
\text{Tr}_{q^n/q}(z) = z + z^q + z^{q^2} + \cdots + z^{q^{n-1}}, \quad \forall z \in \mathbb{F}_q^n.
\]

In particular, if \( q = p \), then \( \text{Tr}_{q^n/q} \) is called the absolute trace.

### 2.1 Cubic polynomials over \( \mathbb{F}_q \)

Let \( q = p^e \) be a prime power, where \( p \neq 3 \) is a prime. Let \( f(x) = x^3 + cx + d \) be a cubic polynomial over \( \mathbb{F}_q \), and let \( \gamma_1, \gamma_2, \gamma_3 \) be its roots in some extension field of \( \mathbb{F}_q \). The discriminant of \( f \) is defined by

\[
\Delta_f := (\gamma_1 - \gamma_2)^2(\gamma_2 - \gamma_3)^2(\gamma_3 - \gamma_1)^2,
\]

which equals \(-4c^3 - 27d^2\) for all \( q \). In particular, when \( q \) is even, we have \( \Delta_f = d^2 \).

**Lemma 2.1.** If \( q \equiv 1 \pmod{3} \) with \( q \) odd, then \(-3\) is a nonzero square in \( \mathbb{F}_q \).

**Proof.** Let \( q = p^e \). In the case \( p \equiv 2 \pmod{3} \), we have \( e \) is even, and so \(-3\) is a nonzero square in \( \mathbb{F}_q \). In the case \( p \equiv 1 \pmod{3} \), by the quadratic reciprocity law we have

\[
\left(\frac{-3}{p}\right) = \left(\frac{-1}{p}\right) \left(\frac{3}{p}\right) = (-1)^{(p-1)/2}(-1)^{3-1/2}(p-1)^2 = \left(\frac{p}{3}\right) = 1.
\]

Here \( \left(\frac{z}{p}\right) \) is the Legendre symbol. Hence \(-3\) is a square in \( \mathbb{F}_p \) and also a square in \( \mathbb{F}_q \). \( \square \)

We shall need the following theorem giving the nonexistence condition for the roots of \( f \) in \( \mathbb{F}_q \) in various situations.

**Theorem 2.2** ([9, 23]). Let \( q \) be a prime power with \( q \equiv 1 \pmod{3} \). Suppose that \( f(x) = x^3 + cx + d \) is a polynomial over \( \mathbb{F}_q \) with discriminant \( \Delta_f \neq 0 \).

1. If \( q \) is odd, and write \(-3 = \alpha^2 \) for some \( \alpha \in \mathbb{F}_q \), then \( f \) has no roots in \( \mathbb{F}_q \) if \( \Delta_f \) is a square in \( \mathbb{F}_q \), say \( \Delta_f = 81\beta^2 \) for some \( \beta \in \mathbb{F}_q \), and \( 2^{-1}(-d + \alpha^2) \) is not a cube in \( \mathbb{F}_q \).
(ii) If \( q \) is even, then \( f \) has no roots in \( \mathbb{F}_q \) if \( \text{Tr}_{q/2}(c^3 d^{-2}) = \text{Tr}_{q/2}(1) \), and the roots \( t_1, t_2 \) of \( t^2 + dt + c^3 = 0 \) are not cubes in \( \mathbb{F}_q \).

Lemma 2.3. Let \( q \) be a prime power with \( q \equiv 1 \pmod{3} \) and \( \theta \) a non-cubic element of \( \mathbb{F}^*_q \). Then the equation \( x^3 + \theta y^3 + \theta^2 z^3 - 3\theta xyz = 0 \) has a unique solution in \( \mathbb{F}_q \), i.e., \( x = y = z = 0 \).

Proof. If \( z = 0 \), then the equation is reduced to \( x^3 + \theta y^3 = 0 \). Since \( \theta \) is not a cube, the above equation has solutions in \( \mathbb{F}_q \) if and only if \( x = y = 0 \). Similarly, if \( x = 0 \) or \( y = 0 \), the original equation has solutions in \( \mathbb{F}_q \) for \( x, y, z \) if and only if \( x = y = z = 0 \). So it is enough to show that the polynomial

\[
f(x) := x^3 - 3\theta yzx + \theta y^3 + \theta^2 z^3
\]

has no roots in \( \mathbb{F}_q \) for any \( y, z \in \mathbb{F}^*_q \).

Case 1. Assume \( q \) is odd. The discriminant of \( f \) is

\[
\Delta_f = -4((3\theta yz)^3 - 27(\theta y^3 + \theta^2 z^3)^2) = (-3) \cdot 9(\theta y^3 - \theta^2 z^3)^2.
\]

By Lemma 2.1, we see that \( \Delta_f \) is a nonzero square in \( \mathbb{F}_q \). Furthermore, if we write \(-3 = \alpha^2 \), and \( \Delta_f = 81\beta^2 = -27\alpha^2 \beta^2 \), then \( \alpha \beta = \pm (\theta y^3 - \theta^2 z^3) \). This implies that \( 2^{-1}(\alpha \beta - (\theta y^3 + \theta^2 z^3)) = \theta y^3 \) or \( \theta^2 z^3 \), neither of which is a cubic in \( \mathbb{F}_q \). Therefore \( f(x) \) has no solutions in \( \mathbb{F}_q \) by Theorem 2.2.

Case 2. Assume \( q \) is even. Then \( q = 2^n \) and \( n \) is even. We have

\[
\text{Tr}_{q/2}\left(\frac{(\theta yz)^3}{(\theta y^3 + \theta^2 z^3)^2}\right)\text{Tr}_{q/2}\left(\frac{\theta y^3}{\theta y^3 + \theta^2 z^3} + \frac{\theta^2 y^6}{(\theta y^3 + \theta^2 z^3)^2}\right) = 0 = \text{Tr}_{q/2}(1).
\]

Moreover, the equation \( t^2 + (\theta y^3 + \theta^2 z^3)t + (\theta yz)^3 = 0 \) has solutions \( t_1 = \theta y^3 \) and \( t_2 = \theta^2 z^3 \), neither of which is a cube in \( \mathbb{F}_q \). Using Theorem 2.2 again, we conclude that \( f(x) \) has no solutions in \( \mathbb{F}_q \).

2.2 An embedded generalized hexagon in \( \text{PG}(7, q) \)

Let \( \mathcal{I} \) be an point-line incidence geometry with point set \( \mathcal{P} \), line set \( \mathcal{L} \) and incidence relation \( \mathcal{I} \subseteq \mathcal{P} \times \mathcal{L} \). The incidence graph of \( \mathcal{I} \) is the graph with vertex set \( \mathcal{P} \cup \mathcal{L} \), where adjacency is given by the incidence relation \( \mathcal{I} \). A generalized hexagon is a point-line geometry such that its incidence graph has diameter 6 and girth 12. A generalized hexagon is said to have order \((s, t)\) if every line is incident with exactly \(s+1\) points and if every point is incident with precisely \(t+1\) lines. A quick example of a generalized hexagon is the flag geometry \( \mathcal{I} \) of a projective plane \( \Pi \) of order \( s \) defined as follows. The points of \( \mathcal{I} \) are the flags of \( \Pi \) (i.e., the incident point-line pairs); the lines of \( \mathcal{I} \) are the points and lines of \( \Pi \). Incidence between points and lines of \( \mathcal{I} \) is reverse containment. It follows that \( \mathcal{I} \) is a generalized hexagon of order \((s, 1)\). We refer the reader to [22] for more background information about generalized hexagons.

Let \( \mathcal{S}_{2,2} \) be the Segre variety of \( \text{PG}(8, q) \) consisting of the \((q^2+q+1)^2\) points represented by

\[
(a_1 b_1, a_1 b_2, a_1 b_3, a_2 b_1, a_2 b_2, a_2 b_3, a_3 b_1, a_3 b_2, a_3 b_3),
\]

(2.1)
where \( a_i, b_i \in \mathbb{F}_q, i = 1, 2, 3 \), with \( (a_1, a_2, a_3) \neq (0, 0, 0) \) and \( (b_1, b_2, b_3) \neq (0, 0, 0) \). By means of the map
\[
\rho : M = (m_{ij}) \in \mathcal{M}_{3,3}(q) \mapsto (m_{11}, m_{12}, m_{13}, m_{21}, m_{22}, m_{31}, m_{32}, m_{33}) \in \mathbb{F}_q^9,
\]
points of \( \mathcal{S}_{2,2} \) correspond to rank one \( 3 \times 3 \) matrices over \( \mathbb{F}_q \). Moreover, \( \mathcal{S}_{2,2} \) is contained in the parabolic quadric \( \mathcal{Q}(8, q) \) given by
\[
X_2X_4 - X_1X_5 + X_3X_7 - X_1X_9 + X_6X_8 - X_5X_9 = 0.
\]
There is a group, say \( G \), isomorphic to \( \text{PGL}(3, q) \) fixing both \( \mathcal{S}_{2,2} \) and \( \mathcal{Q}(8, q) \). This can be seen by the map
\[
\rho^{-1}(X) \mapsto A\rho^{-1}(X)A^{-1}, \ \forall A \in \text{GL}(3, q), X \in \mathcal{S}_{2,2} \cap \mathcal{Q}(8, q).
\]
Such a group fixes the point of \( \text{PG}(8, q) \) corresponding to the \( 3 \times 3 \) identity matrix and the hyperplane \( \Pi : X_1 + X_5 + X_9 = 0 \). Note that \( \Pi \cap \mathcal{Q}(8, q) \) is hyperbolic, elliptic or a cone, according to whether \( q \equiv 1, -1, \) or 0 (mod 3).

Assume that \( q \equiv 1 \pmod{3} \) and denote by \( \mathcal{Q}^+(7, q) \) the hyperbolic quadric obtained by intersecting \( \mathcal{Q}(8, q) \) with \( \Pi \). Let \( \perp \) be the polarity of \( \Pi \) associated with \( \mathcal{Q}^+(7, q) \). By [21, pp. 99–100], the set \( \Pi \cap \mathcal{S}_{2,2} \) consists of \( (q + 1)(q^2 + q + 1) \) points and \( 2(q^2 + q + 1) \) lines of a thin hexagon, say \( \Gamma \); the hexagon \( \Gamma \) corresponds to the point-line flag geometry of \( \text{PG}(2, q) \). Every line of \( \Gamma \) has \( q + 1 \) points of \( \Gamma \). Through a point \( x \) of \( \Gamma \) there pass two lines of \( \Gamma \) spanning a plane and we will denote this plane by \( \pi_x \). It is readily seen that \( \pi_x \subset \mathcal{Q}^+(7, q) \), for \( x \in \Gamma \). The incidence graph of \( \Gamma \) is the girth 12 bipartite graph where the two parts are the points and the lines of \( \Gamma \) and adjacency is given by incidence. The distance between points and lines of \( \Gamma \) is that between two vertices of the incidence graph of \( \Gamma \).

**Lemma 2.4.** The set of \( 2(q + 1) \) lines of \( \Gamma \) having distance 1 or 3 from a point \( x \in \Gamma \) span the hyperplane \( x^\perp \) of \( \Pi \).

**Proof.** By [21, Lemma 1], it is enough to show that these \( 2(q + 1) \) lines are contained in the hyperplane \( x^\perp \). To see this fact observe that if \( r_1, r_2 \) are the two lines of \( \Gamma \) through \( x \), then \( r_1, r_2 \subset \pi_x \subset x^\perp \). If \( \ell \) is a line of \( \Gamma \) and \( d(x, \ell) = 3 \), then \( \ell \) is incident with \( r_1 \) or \( r_2 \) in a point \( z \) and \( \ell \subset \pi_z \subset x^\perp \). \( \square \)

It follows from the previous lemma that the lines of \( \Gamma \) at distance 5 from \( x \) and the points of \( \Gamma \) at distance 6 from \( x \) are not contained in \( x^\perp \).

Let \( U_i \) be the point of \( \text{PG}(8, q) \) having 1 in the \( i \)-th position and 0 elsewhere.

**Lemma 2.5.** If \( x \) is a point of \( \Gamma \), then \( \pi_x^\perp \) meets \( \Gamma \) precisely in the two lines of \( \Gamma \) through \( x \).

**Proof.** Since the group \( G \) acts transitively on points of \( \Gamma \) (by Lemma 3.1), we may assume without loss of generality that \( x \) is the point \( U_3 \). Then some easy calculations show that the 4-dimensional projective space \( X_4 = X_7 = X_8 = 0 \) of \( \Pi \), i.e. \( \pi_{U_3}^\perp \), meets \( \Gamma \) precisely in the two lines of \( \Gamma \) through \( U_3 \). \( \square \)
An apartment of $\Gamma$ consists of $6q$ points and 6 lines of $\Gamma$ forming an ordinary 6-gon. By [21, Lemma 2] an apartment of $\Gamma$ spans a 5-dimensional projective space of $\Pi$.

**Lemma 2.6.** If $x, y$ are distinct points of $\Gamma$, then $\pi_x \cap \pi_y$ is either a line of $\Gamma$ or empty, according to whether $d(x, y)$ equals 2, 4 or 6, respectively.

**Proof.** Let $x, y$ be distinct points of $\Gamma$ and let $\ell_1, \ell_2$ be the two lines of $\Gamma$ through $y$. If $d(x, y) = 2$, then $\pi_x \cap \pi_y = \langle x, y \rangle$. If $d(x, y) = 4$, then we may assume that $d(x, \ell_1) = 3$ and $d(x, \ell_2) = 5$. Hence there is a point $z \in \ell_1$ such that $d(x, z) = 2$. Since $\ell_2 \not\subset x^\perp$, it follows that $\pi_y \cap x^\perp = \ell_1$ and therefore $\pi_x \cap \pi_y = \{z\}$. If $d(x, y) = 6$, then $d(x, \ell_i) = 5$, $i = 1, 2$, and hence there are four points $z_1, z_2, z_3, z_4$ of $\Gamma$ such that $z_i \in \ell_i$, with $d(x, z_i) = 4$, $i = 1, 2$, and $d(x, z_3) = d(z_1, z_3) = d(x, z_4) = d(z_2, z_4) = 2$. The points $x, z_4, z_2, y, z_1, z_3$ are the vertices of an apartment of $\Gamma$. Since $\langle x, z_4, z_2, y, z_1, z_3 \rangle \simeq PG(5, q)$, it follows that $|\pi_x \cap \pi_y| = 0$. \hfill \Box

### 3 The construction

Assume $q \equiv 1 \pmod{3}$ and take the notation introduced in the previous section. Set

$$O = \bigcup_{x \in \Gamma} \pi_x.$$  

By Lemma 2.6 if $x, y \in \Gamma, x \neq y$, and $|\pi_x \cap \pi_y| \neq 0$, then $\pi_x \cap \pi_y \subset \Gamma$. Hence $|O| = (q^2 - q)(q + 1)(q^2 + q + 1) + (q + 1)(q^2 + q + 1) = (q^2 + q + 1)(q^3 + 1)$. This shows that $O$ has the correct size of a $(q^3 + q + 1)$-void of $Q^+(7, q)$ and we will show it is indeed a $(q^3 + q + 1)$-void.

We first describe the orbits of the group $G$ on the point set of $Q^+(7, q)$.

Let $\omega$ be a primitive element of $\mathbb{F}_q$, i.e., $\mathbb{F}^*_q = \langle \omega \rangle$.

**Lemma 3.1.** The group $G$ has 5 orbits on points of $Q^+(7, q)$.

1. The orbit $O_1$ consists of the $(q + 1)(q^2 + q + 1)$ points of $\Gamma$; a representative for $O_1$ is $P_1 = U_3$ and $U_3^\perp$ contains exactly $2(q + 1)$ lines of $\Gamma$.

2. The orbit $O_2$ consists of the $(q^3 - q)(q^2 + q + 1)$ points of $O \setminus \Gamma$; a representative for $O_2$ is $P_2 = U_2 + U_6$ and $P_2^\perp$ contains exactly 2 lines of $\Gamma$.

3. The orbit $O_3$ has size $q^3(q + 1)(q^2 + q + 1)/3$; a representative for $O_3$ is $P_3 = U_1 + \omega^{2^{i-4}}U_5 + \omega^{2^{i-1}}U_9$ and $P_3^\perp$ contains exactly 6 lines of $\Gamma$.

4. The orbit $O_i$, $i = 4, 5$, has $q^3(q^2 - 1)(q - 1)/3$ points; a representative for $O_4$ is $P_4 = U_2 + U_6 + \omega U_7$ and for $O_5$ is $P_5 = U_3 + \omega U_4 + \omega U_8$; $P_i^\perp$, $i = 4, 5$, contains no line of $\Gamma$.

**Proof.** We shall find it helpful to work with the elements of $PGL(3, q)$ as matrices in $GL(3, q)$ and the points of $PG(7, q)$ as $3 \times 3$ matrices with trace zero.
1. Let $A \in \text{GL}(3, q)$ and assume that $A\rho^{-1}(U_3)A^{-1} = \lambda \rho^{-1}(U_3)$ for some $\lambda \in \mathbb{F}_q^*$. This can be written explicitly as
\[
\begin{pmatrix}
0 & 0 & a_{11} \\
0 & 0 & a_{21} \\
0 & 0 & a_{31}
\end{pmatrix}
= \lambda \begin{pmatrix}
a_{31} & a_{32} & a_{33} \\
0 & 0 & 0 \\
0 & 0 & 0
\end{pmatrix},
\]
which implies that $a_{11} = \lambda a_{33}$ and $a_{21} = a_{31} = a_{32} = 0$. Since $A \in \text{GL}(3, q)$, then $a_{22}a_{33} \neq 0$. It follows that the stabilizer of $P_1$ in $\text{GL}(3, q)$ has size $q^3(q - 1)^3$ and so
\[
|O_1| = \frac{|\text{GL}(3, q)|}{q^3(q - 1)^3} = (q + 1)(q^2 + q + 1).
\]
The fact that $U_3^\perp$ contains $2(q + 1)$ lines of $\Gamma$ follows from Lemma 2.4.

2. Let $A \in \text{GL}(3, q)$ with $A\rho^{-1}(P_2)A^{-1} = \lambda \rho^{-1}(P_2)$ for some $\lambda \in \mathbb{F}_q^*$. Then $a_{21} = a_{31} = a_{32} = 0$, $a_{12} = \lambda a_{23}$, $a_{11} = \lambda a_{22}$, $a_{22} = \lambda a_{33}$, and $a_{33} \neq 0$. Thus
\[
|O_2| = \frac{|\text{GL}(3, q)|}{q^2(q - 1)^2} = q(q^3 - 1)(q + 1).
\]
The point $P_2$ belongs to $\pi_{U_3}$ and hence $P_2^\perp$ contains the two lines $\ell_1, \ell_2$ of $\Gamma$ through $U_3$. Let $\ell$ be a line of $\Gamma$. If $d(U_3, \ell) = 3$ and $\ell \subset P_2^\perp$, then $|\ell \cap \ell_1| = 1$ and $\langle \ell, \ell_1 \rangle, \langle P_2, \ell \rangle, \langle \ell_1, \ell_2 \rangle$ are three planes of $\mathcal{Q}^+(7, q)$ spanning a solid and pairwise intersecting in a line. It follows that the solid is contained in $\mathcal{Q}^+(7, q)$. Therefore $\ell \subset \pi_{U_3}^\perp$, contradicting Lemma 2.5. If $d(U_3, \ell) = 5$ and $\ell \subset P_2^\perp$, then there is a line $\ell'$ incident with $\ell$ and with $\ell_1$. Hence $d(U_3, \ell') = 3$ and $\ell' \subset P_2^\perp$. Thus, as above, $\ell' \subset \pi_{U_3}^\perp$, contradicting Lemma 2.5.

3. Let $A \in \text{GL}(3, q)$ with $A\rho^{-1}(P_3)A^{-1} = \lambda \rho^{-1}(P_3)$ for some $\lambda \in \mathbb{F}_q^*$. If $\lambda = 1$, then $a_{12} = a_{13} = a_{21} = a_{23} = a_{31} = a_{32} = 0$ and $a_{11}a_{22}a_{33} \neq 0$. If $\lambda = \omega^{\frac{q+1}{2}}$, then $a_{11} = a_{13} = a_{21} = a_{23} = a_{31} = a_{33} = 0$ and $a_{12}a_{23}a_{31} \neq 0$. If $\lambda = \omega^{\frac{q(q-1)}{4}}$, then $a_{11} = a_{12} = a_{22} = a_{23} = a_{31} = a_{33} = 0$ and $a_{13}a_{21}a_{32} \neq 0$. If $\lambda \notin \{1, \omega^{\frac{q+1}{2}}, \omega^{\frac{q(q-1)}{4}}\}$, then $A = 0$ which is not in $\text{GL}(3, q)$. Therefore,
\[
|O_3| = \frac{|\text{GL}(3, q)|}{3(q - 1)^3} = \frac{q^3(q + 1)(q^2 + q + 1)}{3}.
\]
The hyperplane $P_3^\perp$ of $\Pi$ contains the 5-dimensional projective space $X_1 = X_5 = X_9 = 0$ which meets $\mathcal{Q}^+(7, q)$ in a $\mathcal{Q}^+(5, q)$ and intersects $\Gamma$ precisely in the apartment $\mathcal{A}$ given by the 6 lines $\langle U_2, U_3 \rangle, \langle U_3, U_6 \rangle, \langle U_6, U_4 \rangle, \langle U_4, U_7 \rangle, \langle U_7, U_8 \rangle, \langle U_8, U_2 \rangle$. A line $s$ of $\Gamma$ disjoint from $\mathcal{A}$ cannot be contained in $P_3^\perp$, otherwise $s \cap \mathcal{Q}^+(5, q)$ would be a point of $\Gamma$ not contained in $\mathcal{A}$. Similarly, a line $s$ of $\Gamma$ incident with a line $r$ of $\mathcal{A}$ cannot be contained in $P_3^\perp$, otherwise through $r$ there would be three planes of $\mathcal{Q}^+(7, q)$ and necessarily two of these three planes would span a solid of $\mathcal{Q}^+(7, q)$. In this case it follows that there exists a line $r'$ of $\mathcal{A}$ incident with $r$ such that $s \subset \langle r, r' \rangle^\perp$, contradicting Lemma 2.5.
4. Assume \( A \in \text{GL}(3, q) \) with \( A p^{-1}(P_4)A^{-1} = \lambda p^{-1}(P_4) \) for some \( \lambda \in \mathbb{F}_q^* \). Then \( \lambda^3 = 1 \), \( a_{11} = \lambda^2 a_{33}, a_{22} = \lambda a_{33}, a_{12} = \lambda a_{23}, a_{31} = \lambda^2 \omega a_{23}, a_{24} = \lambda^2 \omega a_{13}, \) and \( a_{32} = \lambda \omega a_{13} \).

With these conditions, we have

\[
\det(A) = a_{33}^2 + \omega a_{23}^2 + \omega^2 a_{13}^2 - 3\omega a_{13}a_{23}a_{33}.
\]

Since \( \det(A) \neq 0 \), by Lemma 2.3, the only restriction on \( \{a_{13}, a_{23}, a_{33}\} \) is \( (a_{13}, a_{23}, a_{33}) \neq (0, 0, 0) \). Therefore,

\[
|O_3| = \frac{|\text{GL}(3, q)|}{3(q^3 - 1)} = \frac{q^3(q^2 - 1)(q - 1)}{3}.
\]

The computation for the orbit of \( P_3 \) is similar and we omit it. To see that \( P_4 \) and \( P_5 \) are not in the same orbit, assume \( A \in \text{GL}(3, q) \) such that \( A p^{-1}(P_4) = \lambda p^{-1}(P_5)A \) for some \( \lambda \in \mathbb{F}_q^* \). Then \( \lambda^3 \omega = 1 \) which is impossible.

We conclude that \( G \) has five orbits as described above since \( |O_1| + \cdots + |O_5| = (q^3 + 1)\frac{q^2 - 1}{q - 1} \) which equals the number of points of \( Q^+(7, q) \).

The line \( u \) joining \( P_4 \) and \( P_5 \) is secant to \( Q^+(7, q) \) and \( u^\perp \) is the 5-dimensional projective space of \( \Pi \) given by \( \omega X_3 + X_4 + X_5 = \omega X_2 + \omega X_5 + X_7 = 0 \). Furthermore, \( u^\perp \) is disjoint from \( \Gamma \). Indeed, the point given in (2.1) belongs to \( u^\perp \) if and only if

\[
\begin{align*}
  a_1b_1 + a_2b_2 + a_3b_3 &= 0 \\
  \omega a_1b_2 + \omega a_2b_3 + a_3b_1 &= 0 \\
  \omega a_1b_3 + a_2b_1 + a_3b_2 &= 0.
\end{align*}
\]

The system (3.1) has no non-trivial solutions since

\[
\det\begin{pmatrix}
  b_1 & b_2 & b_3 \\
  \omega b_2 & \omega b_3 & b_1 \\
  \omega b_3 & b_1 & b_2
\end{pmatrix} = 3\omega b_1b_2b_3 - b_1^3 - \omega b_2^3 - \omega^2 b_3^3 = 0,
\]

which implies that \( (b_1, b_2, b_3) = (0, 0, 0) \) by Lemma 2.3. It follows that no line of \( \Gamma \) is contained in \( P_4^\perp \) or in \( P_5^\perp \).

\( \square \)

**Remark 3.2.** By Lemma 3.1 and (2.2), the set \( \mathcal{O} \) consists precisely of the points of \( \Pi \) corresponding to \( 3 \times 3 \) matrices over \( \mathbb{F}_q \) having rank at most 2.

We are now ready to prove the main theorem.

**Theorem 3.3.** The set \( \mathcal{O} \) is a \((q^2 + q + 1)\)-ovoid of \( Q^+(7, q) \).

**Proof.** We show that \( |P_i^\perp \cap \mathcal{O}| \) equals \( q^4 + q^3 + q^2 + q + 1 \) if \( i = 1, 2 \) or \( (q^2 + 1)(q^2 + q + 1) \) if \( i = 3, 4, 5 \).

The hyperplane \( P_4^\perp \) of \( \Pi \) contains \( 2(q + 1) \) lines of \( \Gamma \) and hence

\[
|P_4^\perp \cap \Gamma| = 2q^2 + 2q + 1.
\]
Let \( x \) be a point of \( \Gamma \). If \( x = P_1 \) or \( d(x, P_1) = 2 \), then \( \pi_x \subseteq P_1^\perp \). If \( d(x, P_1) = 4 \), then \( \pi_x \cap P_1^\perp \) is a line of \( \Gamma \) contained in \( P_1^\perp \), whereas if \( d(x, P_1) = 6 \), then \( \pi_x \cap P_1^\perp \) is a line with two points of \( \Gamma \). Hence
\[
|P_1^\perp \cap (\mathcal{O} \setminus \Gamma)| = (2q + 1) \times (q^2 - q) + q^3 \times (q - 1) = q^4 + q^3 - q^2 - q
\]
and therefore \( |P_1^\perp \cap \mathcal{O}| = q^4 + q^3 + q^2 + q + 1 \).

Assume that the hyperplane \( P_2^\perp \) of \( \Pi \) contains the two lines of \( \Gamma \) contained in \( \pi_y \). It follows that
\[
|P_2^\perp \cap \Gamma| = (q + 1)^2.
\]
Let \( x \) be a point of \( \Gamma \). If \( x = y \), then \( \pi_x \subseteq P_2^\perp \). If \( d(x, y) = 2 \), then \( \pi_x \cap P_2^\perp \) is a line of \( \Gamma \) contained in \( P_2^\perp \). If \( d(x, y) \geq 4 \), then either \( x \in P_2^\perp \) and \( \pi_x \cap P_2^\perp \) is a line with one point of \( \Gamma \), or \( x \notin P_2^\perp \) and \( \pi_x \cap P_2^\perp \) is a line with two points of \( \Gamma \). Hence
\[
|P_2^\perp \cap (\mathcal{O} \setminus \Gamma)| = (q^2 - q) + q^2 \times q + (q^3 + q^2) \times (q - 1) = q^4 + q^3 - q
\]
and therefore \( |P_2^\perp \cap \mathcal{O}| = q^4 + q^3 + q^2 + q + 1 \).

If the hyperplane \( P_3^\perp \) of \( \Pi \) contains the apartment \( \mathcal{A} \) of \( \Gamma \), then
\[
|P_3^\perp \cap \Gamma| = (q - 1)^2 + 6q = q^2 + 4q + 1.
\]
Indeed there are exactly \( 2(q - 1)^2 \) lines of \( \Gamma \) intersecting \( P_3^\perp \) in a point not belonging to \( \mathcal{A} \). Let \( x \) be a point of \( \Gamma \). If \( x \in \mathcal{A} \), then either \( x \) is a vertex of \( \mathcal{A} \) and \( \pi_x \subseteq P_3^\perp \) or \( x \) is not a vertex of \( \mathcal{A} \) and \( \pi_x \cap P_3^\perp \) is a line of \( \mathcal{A} \) that hence is contained in \( P_3^\perp \). If \( x \notin \mathcal{A} \), then either \( x \in P_3^\perp \) and \( \pi_x \cap P_3^\perp \) is a line with one point of \( \Gamma \), or \( x \notin P_3^\perp \) and \( \pi_x \cap P_3^\perp \) is a line with two points of \( \Gamma \). Hence
\[
|P_3^\perp \cap (\mathcal{O} \setminus \Gamma)| = 6 \times (q^2 - q) + (q - 1)^2 \times q + (q^3 + q^2 - 2q) \times (q - 1) = q^4 + q^3 + q^2 - 3q
\]
and therefore \( |P_3^\perp \cap \mathcal{O}| = (q^2 + 1)(q^2 + q + 1) \).

If \( i \in \{4, 5\} \), then no line of \( \Gamma \) is contained in the hyperplane \( P_i^\perp \) of \( \Pi \). Hence
\[
|P_i^\perp \cap \Gamma| = q^2 + q + 1.
\]
Let \( x \) be a point of \( \Gamma \). In this case either \( x \in P_i^\perp \) and \( \pi_x \cap P_i^\perp \) is a line with one point of \( \Gamma \), or \( x \notin P_i^\perp \) and \( \pi_x \cap P_i^\perp \) is a line with two points of \( \Gamma \). Hence
\[
|P_i^\perp \cap (\mathcal{O} \setminus \Gamma)| = (q^2 + q + 1) \times q + (q^3 + q^2 + q) \times (q - 1) = q^4 + q^3 + q^2
\]
and therefore \( |P_i^\perp \cap \mathcal{O}| = (q^2 + 1)(q^2 + q + 1) \).

\[\square\]

4 Concluding remarks

4.1 Other known examples of \( m \)-ovoids of \( Q^+(7, q) \)

To the best of our knowledge, there are further known \( m \)-ovoids of \( Q^+(7, q) \) not mentioned in Section 1.
Proposition 4.1. There are lines of non-degenerate hyperplane. We explain below that the answer is no.

Consider the parabolic quadric $Q$ of $\mathbb{F}_q$. This is not interesting. However, for $q = 2$, $3$, $4$, $5$, we found $(q^2 + q + 1)$-ovoids of $Q(8, q)$ for $q = 2, 3, 4, 5$. When $q = 2$, the $(q^2 + q + 1)$-ovoid found by the computer is actually an embedded $Q^-(7, q)$. This is not interesting. However, for $q = 3, 4, 5$, a Magma computation shows that there exists a $(q^2 + q + 1)$-ovoid not contained in a hyperplane and we conjecture that this is true for all larger $q$.
Conjecture 4.2. There exists a \((q^2 + q + 1)\)-ovoid of \(\mathcal{Q}(8, q)\) which is not contained in a hyperplane for any prime power \(q > 2\).
